OUTLINE

Limitations of decision trees

Markov model description

Markov model features

Markov chain versus process

Discounting and Inflation

LIMITATIONS OF DECISION TREE (1)

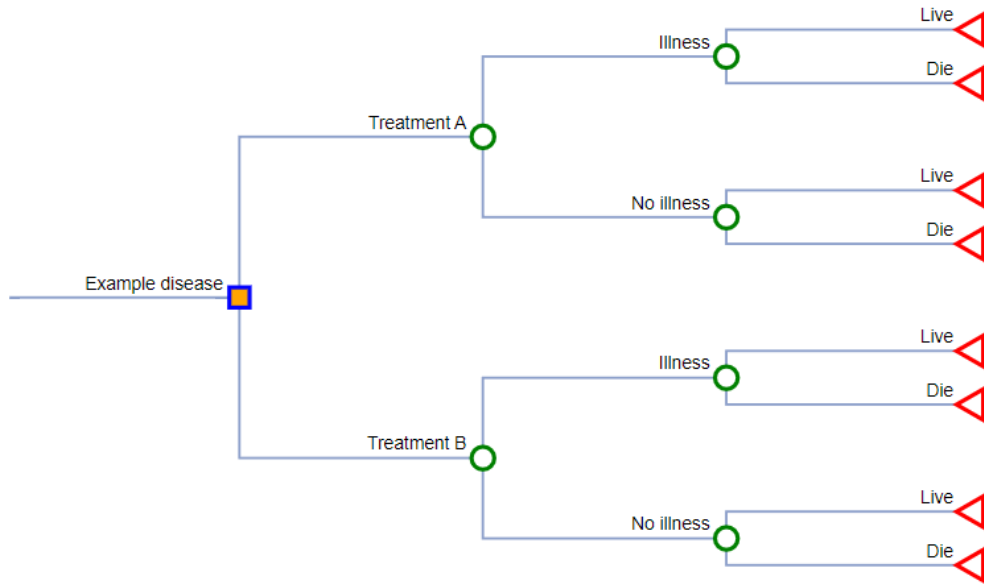

Chronic diseases have long time horizons

Can't possibly capture all the re-entry points in a decision tree (becomes repetitive)

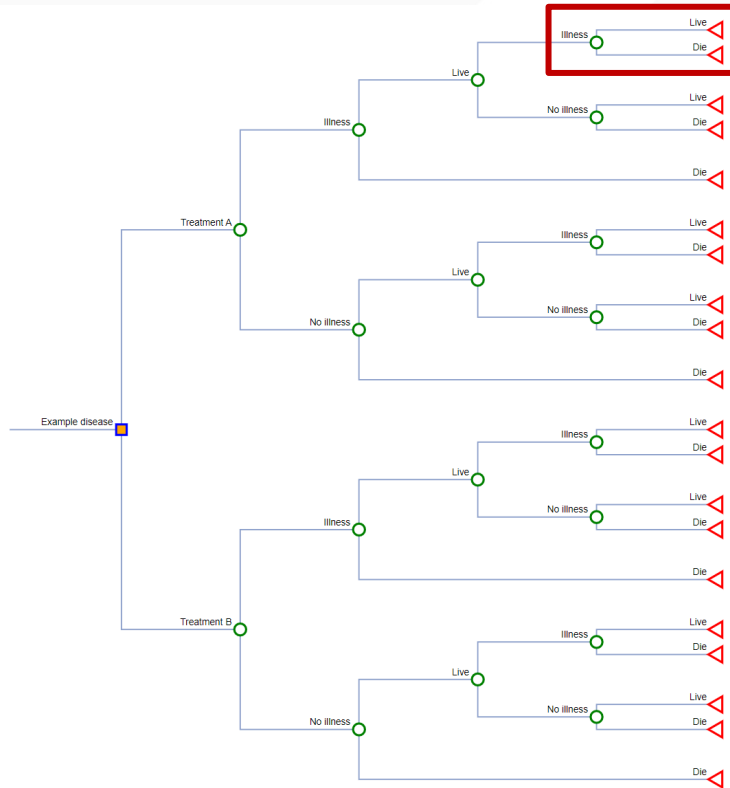

Markov re-entry nodes are convenient; decision branches are messy

Markov models are good alternatives to decision trees

LIMITATIONS OF DECISION TREE (2)

LIMITATIONS OF DECISION TREE (3)

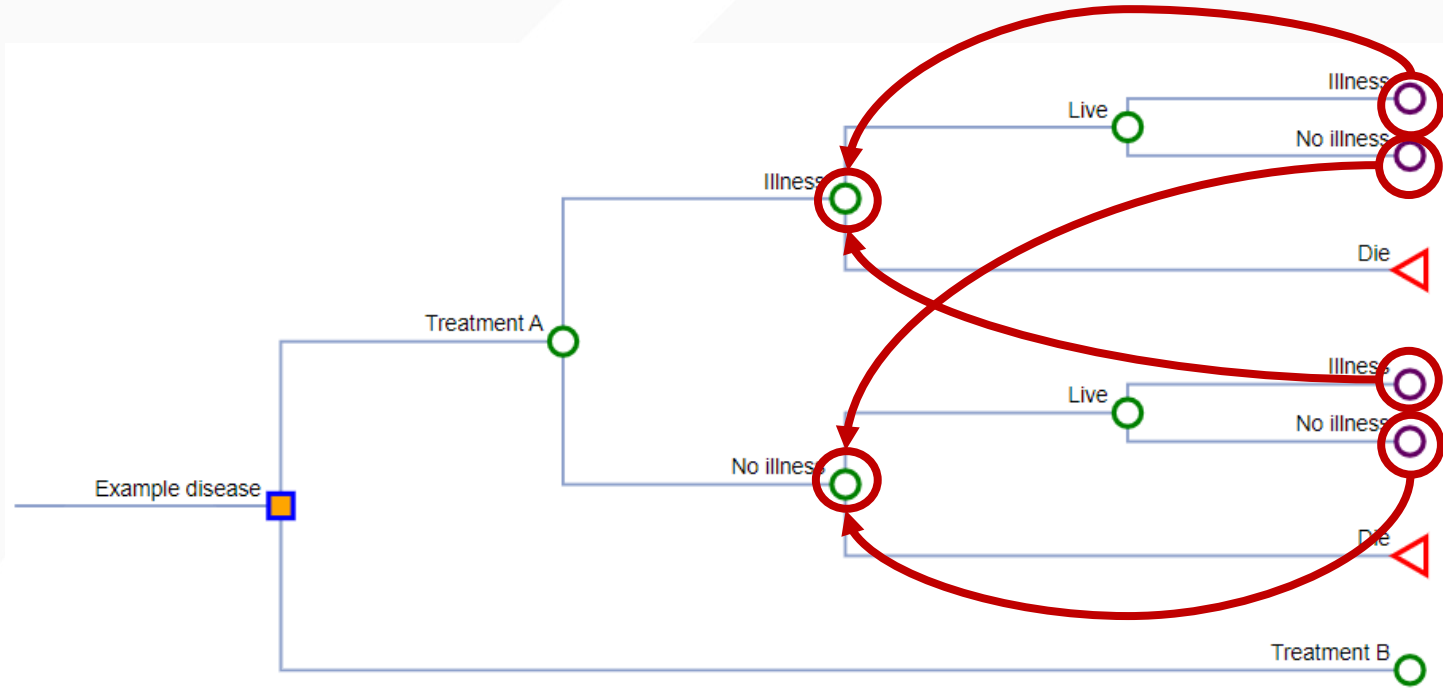

This part of the decision tree is a repeat of the Illness node.

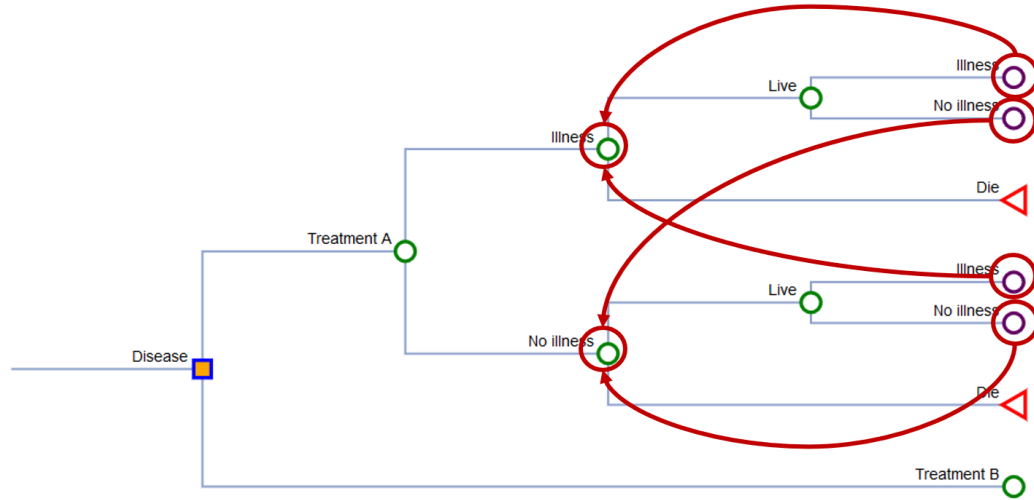

When a subject has an illness, they can live or die. If they live and have another illness, they can live or die once again.

This cycle repeats itself over and over.

LIMITATIONS OF DECISION TREE (4)

LIMITATIONS OF DECISION TREE (5)

Well → Well

Well → Illness

Well → Death

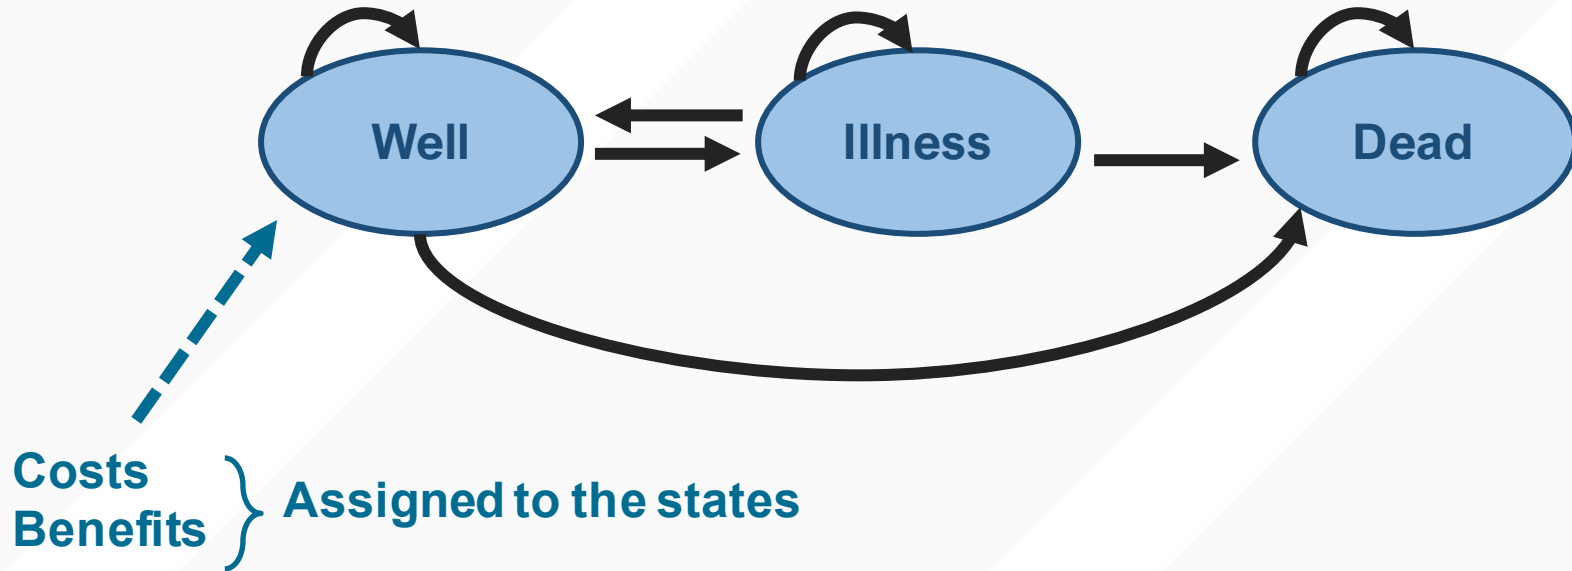

Illness → Illness

Illness → Well

Illness → Death

Death → Death

MARKOV MODEL STRUCTURE

MARKOV MODEL - DESCRIPTION

Markov models are state-transition models

Useful when modeling chronic diseases

Each state represents a disease stage (or process)

Costs and benefits are assigned to each state

Can apply discounting

Individual subject can only be in one state at any cycle

MARKOV MODEL – DISEASE STATES

Asymptomatic state

Disease state

Absorbing state

MARKOV MODEL – TRANSITION PROBABILITIES (1)

Well → Well
Well → Illness
Well → Death

tp6

} 100%

Death → Death tp7

If you have tp2 and tp3, then
 $tp1 = 1 - tp2 - tp3$

MARKOV MATRIX

| From / To | Well | Illness | Dead |
|-----------|------------------------|------------------------|------|
| Well | tp1 (1 - tp2 - tp3) | tp2 | tp3 |
| Illness | tp5 | tp4 (1 - tp5 - tp6) | tp6 |
| Dead | 0 | 0 | tp7 |

MARKOV MODEL – FEATURES

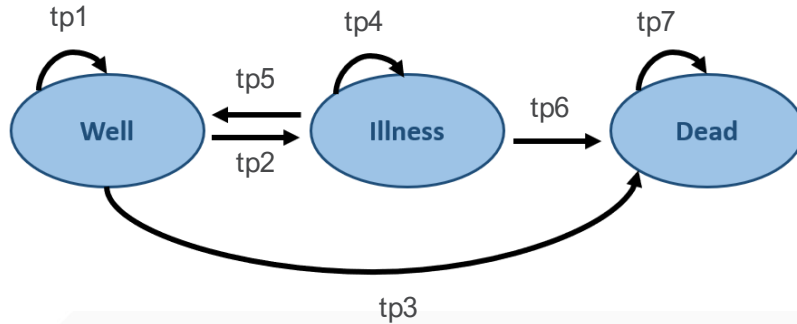

One iteration = Cycle
X-iterations = Time horizon

MARKOV CHAIN VERSUS PROCESS (1)

Markov chain – static transitions

Markov process – dynamic transitions

MARKOV CHAIN VERSUS PROCESS (2)

Markov chain – static transitions

Markov process – dynamic transitions

Transition probabilities remain static

If $tp1 = 0.90$ is cycle 1, then $tp1 = 0.90$ in cycle 2

MARKOV CHAIN VERSUS PROCESS (3)

Markov chain – static transitions

Markov process – dynamic transitions

Transition probabilities change from cycle to cycle

Although $tp1 = 0.90$ is cycle 1, $tp1 = 0.85$ in cycle 2

MARKOV CHAIN VERSUS PROCESS (4)

Markov chain – static transitions

Markov process – dynamic transitions

This is useful when the cohort will have a lower survival over a long period of time

COHORT VERSUS MICROSIMULATIONS (1)

Cohort simulation

Model a group of hypothetical patients at the same time

Time horizon is fixed

Computationally less intensive

Individual or microsimulations (Monte Carlo)

Individuals are modeled through the Markov models one at a time

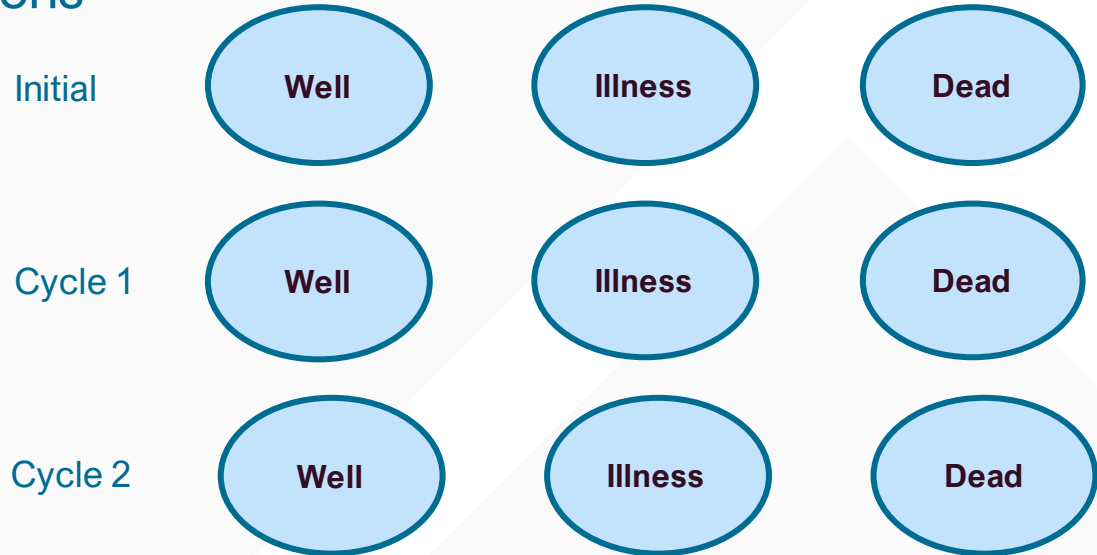

Time for each patient can be short or long

Computationally intensive

COHORT VERSUS MICROSIMULATIONS (1)

Cohort simulation

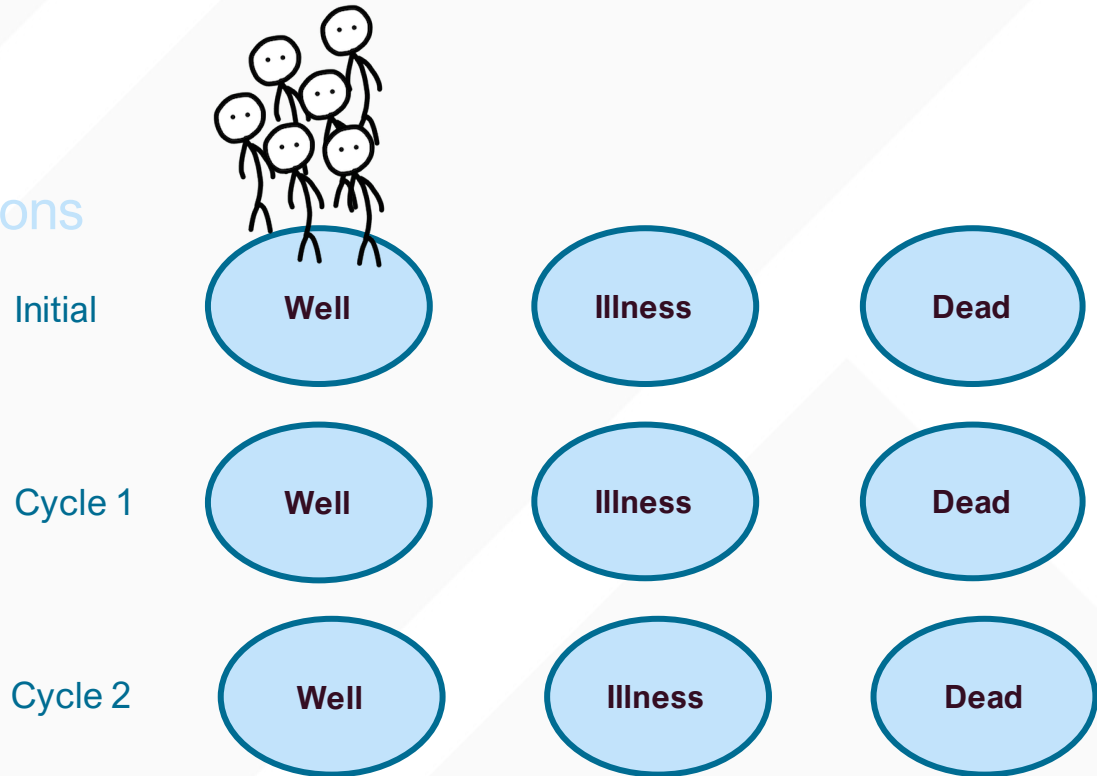

Individual or microsimulations

COHORT VERSUS MICROSIMULATIONS (2)

Cohort simulation

Individual or microsimulations

COHORT VERSUS MICROSIMULATIONS (3)

Cohort simulation

Individual or microsimulations

COHORT VERSUS MICROSIMULATIONS (12)

Cohort simulation

Individual or microsimulations

Estimating transition probabilities

Using existing studies to estimate probabilities for decision models

ESTIMATING TRANSITION PROBABILITIES (1)

Rate – Instantaneous likelihood of transition at any point in time (e.g., 5 events per 100 Person Years)

Probability – Proportion of a cohort that experiences the event over a specific period (e.g., 90% of patients had the event)

To get the transition probabilities in a Markov model using an existing study, estimate the rate, then estimate the probability for the time of interest using the rate

ESTIMATING TRANSITION PROBABILITIES (2)

Estimating the probability from a study:

Probability from study \rightarrow Rate \rightarrow Probability for model

$$Rate = \frac{-\ln(1 - p)}{t}$$

$$Probability = 1 - e^{-rt}$$

p probability

t time

r rate

ESTIMATING TRANSITION PROBABILITIES (3)

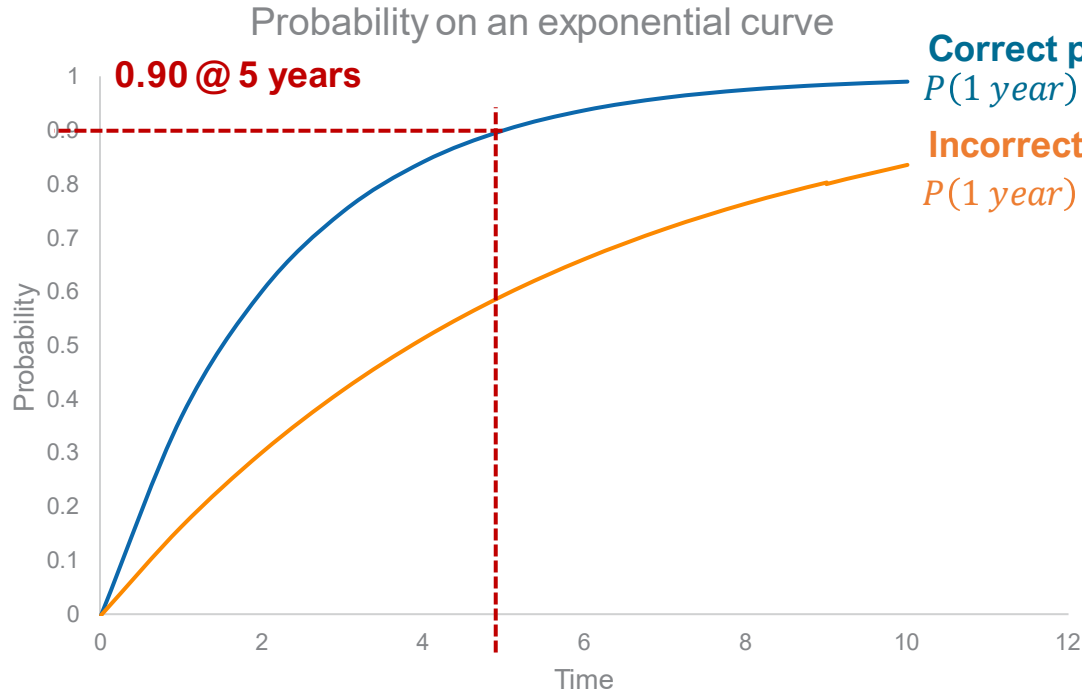

If the 5-year probability of achieving a cure is 90%, what is the 1-year probability?

You can't divide the 5-year probability by 5 (e.g., 90% / 5 = 18% to get the annual rate)

Probability from study \Rightarrow $Rate = \frac{-\ln(1 - p)}{t}$ \Rightarrow $P(t) = 1 - e^{-rt}$

$P(5 \text{ years}) = 90\%$ \Rightarrow $Rate = \frac{-\ln(1 - 0.90)}{5 \text{ years}} = 0.46$ \Rightarrow $P(1 \text{ year}) = 1 - e^{-(0.46)(1 \text{ year})} = 0.37$

ESTIMATING TRANSITION PROBABILITIES (4)

Correct probability

$$P(1 \text{ year}) = 1 - e^{-(0.46)(1 \text{ year})} = 0.37$$

Incorrect probability

$$P(1 \text{ year}) = 1 - e^{-(0.18)(1 \text{ year})} = 0.16$$

ESTIMATING TRANSITION PROBABILITIES (5)

Suppose you had data from a meta-analysis where the relative risk of cure is 2.0 with a drug

What is the 1-year probability of cure using an annual rate of cure that is 0.47? (Hint: Is it not 2 x 0.47)

RR * rate

$$P(t) = 1 - e^{-rt}$$

$$2.0 \times 0.47 = 0.94$$

$$P(1 \text{ year}) = 1 - e^{-(0.94)(1 \text{ year})} = 0.61$$

Discounting and inflation

Adjusting costs and outcomes for long
time horizons

DISCOUNTING AND INFLATION

Net Present Value: Current purchasing power of currency

DISCOUNTING

What is today's value of \$1 10 years from now using a 3% discount rate?

$$V_0 = \frac{V_t}{(1 + r)^t} \quad \rightarrow \quad \$0.74 = \frac{\$1}{(1 + 0.03)^{10}}$$

V_0 = Value in today's term

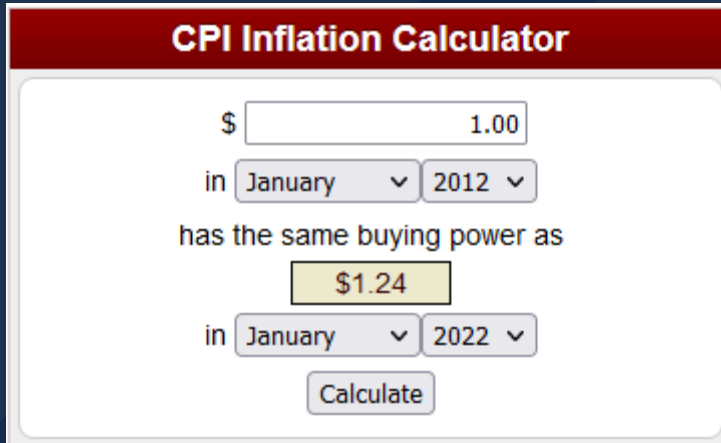

V_t = Value at time t in the future

r = Discount rate

t = Time in the future

INFLATION

What is today's value of \$1 from 10 years ago using the Consumer Price Index?

CPI Inflation Calculator

SETTING UP THE MARKOV MODEL

List all the transitions

Transition states

Well --> Well

$1 - tp(\text{well_illness}) - tp(\text{well_dead})$

Probability

0.83

Remain in the Well state

Well --> Illness

$tp(\text{well_illness})$

0.15

Transition from Well to Illness

Well --> Dead

$tp(\text{well_dead})$

0.02

Transition from Well to Death

Illness --> Illness

$1 - tp(\text{illness_well}) - tp(\text{illness_dead})$

0.65

Remain in the Illness state

Illness --> Well

$tp(\text{illness_well})$

0.30

Transition from Illness to Well

Illness --> Dead

$tp(\text{illness_dead})$

0.05

Transition from Illness to Death

Dead --> Dead

$tp(\text{dead})$

1.00

Remain in Death (Absorbing state)

MARKOV MATRIX

| From / To | Well | Illness | Dead |
|-----------|------|---------|------|
| Well | 0.83 | 0.15 | 0.02 |
| Illness | 0.30 | 0.65 | 0.05 |
| Dead | 0 | 0 | 1.00 |

ASSIGN COSTS AND UTILITIES TO THE STATES

Since the costs and utilities are specific to each state you can list them in a table

| <u>Transition states</u> | <u>Costs</u> | <u>Utility</u> | <u>Description</u> |
|--------------------------|--------------|----------------|--------------------------------|
| Well | \$500.00 | 1.00 | These parameters are fictional |
| Illness | \$2,000.00 | 0.50 | These parameters are fictional |
| Dead | \$0.00 | 0.00 | These parameters are fictional |

MODEL PROPERTIES

Each cycle is 1 year

Simulate for 100 years (or 100 cycles)

Apply an annual discount rate of 3% on costs and outcomes

MATHEMATICAL MODEL

Cohort size

We start at
cell E12

| 1 cycle = 1 year | | Expected probabilities | | | |
|------------------|----|------------------------|---------|--------|-------|
| Cycle | | Well | Illness | Dead | Total |
| | 0 | 1.0000 | 0.0000 | 0.0000 | 1 |
| | 1 | 0.8300 | 0.1500 | 0.0200 | 1 |
| | 2 | 0.7339 | 0.2220 | 0.0441 | 1 |
| | 3 | 0.6757 | 0.2544 | 0.0699 | 1 |
| | 4 | 0.6372 | 0.2667 | 0.0961 | 1 |
| | 5 | 0.6089 | 0.2689 | 0.1222 | 1 |
| | 6 | 0.5860 | 0.2661 | 0.1478 | 1 |
| | 7 | 0.5663 | 0.2609 | 0.1728 | 1 |
| | 8 | 0.5483 | 0.2545 | 0.1972 | 1 |
| | 9 | 0.5314 | 0.2477 | 0.2209 | 1 |
| | 10 | 0.5154 | 0.2407 | 0.2439 | 1 |

MATHEMATICAL MODEL

Cohort size

1

The size of the cohort.
We'll set this at 1.
The cell is G6.

At cycle 0, all subjects will start at the "Well" state.

In the cell, the formula is:

$=\$G\$6 * 1$

The "\$" denotes that the column / row does not change.

| 1 cycle = 1 year | Expected probabilities | | | |
|------------------|------------------------|---------|--------|-------|
| Cycle | Well | Illness | Dead | Total |
| 0 | 1.0000 | 0.0000 | 0.0000 | 1 |
| 1 | 0.8300 | 0.1500 | 0.0200 | 1 |
| 2 | 0.7339 | 0.2220 | 0.0441 | 1 |
| 3 | 0.6757 | 0.2544 | 0.0699 | 1 |
| 4 | 0.6372 | 0.2667 | 0.0961 | 1 |
| 5 | 0.6089 | 0.2689 | 0.1222 | 1 |
| 6 | 0.5860 | 0.2661 | 0.1478 | 1 |
| 7 | 0.5663 | 0.2609 | 0.1728 | 1 |
| 8 | 0.5483 | 0.2545 | 0.1972 | 1 |
| 9 | 0.5314 | 0.2477 | 0.2209 | 1 |
| 10 | 0.5154 | 0.2407 | 0.2439 | 1 |

At cycle 0, zero subjects will start at the "Illness" and "Dead" states.

In these cells, the formulas are:
 $=\$G\$6 * 0$

Based on probability theory the sum of the expected number of subjects should be equal to cell G6. In this case, that will be 1.

CALCULATING EXPECTED PROBABILITIES (1)

$1 - tp(\text{well_illness}) - tp(\text{well_dead})$

$tp(\text{well_illness})$

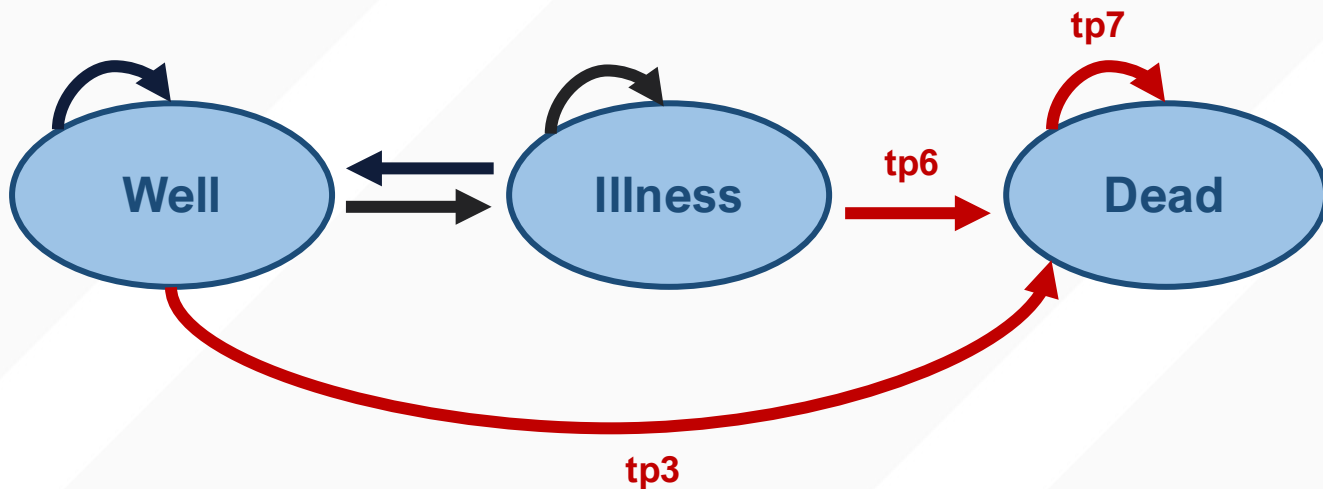

$tp(\text{well_dead})$

1 cycle = 1 year

Expected probabilities

| Cycle | Well | Illness | Dead | Total |
|-------|--------|---------|--------|-------|
| 0 | 1.0000 | 0.0000 | 0.0000 | 1 |
| 1 | 0.8300 | 0.1500 | 0.0200 | 1 |
| 2 | 0.7339 | 0.2220 | 0.0441 | 1 |
| 3 | 0.6757 | 0.2544 | 0.0699 | 1 |
| 4 | 0.6372 | 0.2667 | 0.0961 | 1 |
| 5 | 0.6089 | 0.2689 | 0.1222 | 1 |
| 6 | 0.5860 | 0.2661 | 0.1478 | 1 |
| 7 | 0.5663 | 0.2609 | 0.1728 | 1 |
| 8 | 0.5483 | 0.2545 | 0.1972 | 1 |
| 9 | 0.5314 | 0.2477 | 0.2209 | 1 |
| 10 | 0.5154 | 0.2407 | 0.2439 | 1 |

LIMITATIONS OF DECISION TREES (2)

CALCULATING EXPECTED PROBABILITIES (1)

$1 - tp(\text{well_illness}) - tp(\text{well_dead})$

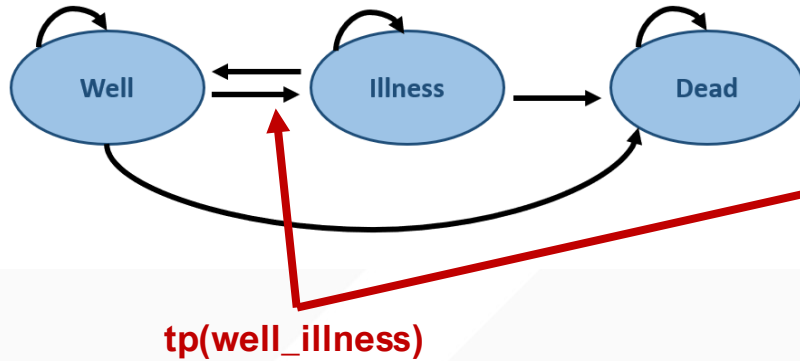

1 cycle = 1 year

Expected probabilities

| Cycle | Well | Illness | Dead | Total |
|-------|--------|---------|--------|-------|
| 0 | 1.0000 | 0.0000 | 0.0000 | 1 |
| 1 | 0.8300 | 0.1500 | 0.0200 | 1 |
| 2 | 0.7339 | 0.2220 | 0.0441 | 1 |
| 3 | 0.6757 | 0.2544 | 0.0699 | 1 |
| 4 | 0.6372 | 0.2667 | 0.0961 | 1 |
| 5 | 0.6089 | 0.2689 | 0.1222 | 1 |

| Total Expected Costs | | | | = | \$31,128.64 |
|----------------------|----------|--------|----------|---|-------------|
| Well | Illness | Dead | Total | | |
| \$500.00 | \$0.00 | \$0.00 | \$500.00 | | |
| \$415.00 | \$300.00 | \$0.00 | \$715.00 | | |
| \$366.95 | \$444.00 | \$0.00 | \$810.95 | | |
| \$337.87 | \$508.77 | \$0.00 | \$846.64 | | |
| \$318.59 | \$533.42 | \$0.00 | \$852.01 | | |
| \$304.44 | \$537.88 | \$0.00 | \$842.31 | | |

| Total Expected QALYs | | | | = | 27.9098 |
|----------------------|---------|--------|--------|---|---------|
| Well | Illness | Dead | Total | | |
| 1.0000 | 0.0000 | 0.0000 | 1.0000 | | |
| 0.8300 | 0.0750 | 0.0000 | 0.9050 | | |
| 0.7339 | 0.1110 | 0.0000 | 0.8449 | | |
| 0.6372 | 0.1272 | 0.0000 | 0.8029 | | |
| 0.6372 | 0.1334 | 0.0000 | 0.7705 | | |
| 0.6089 | 0.1345 | 0.0000 | 0.7433 | | |

Expected utility at cycle 2 is
 $0.7339 * 1 = 0.73$ QALYs

CALCULATING EXPECTED COSTS AND UTILITIES (5)

Sum the costs to get the total expected costs

Sum the QALYs to get the total expected QALYs

| 1 cycle = 1 year | | Expected probabilities | | | |
|------------------|--------|------------------------|--------|-------|--|
| Cycle | Well | Illness | Dead | Total | |
| 0 | 1.0000 | 0.0000 | 0.0000 | 1 | |

| \$283.06 | \$473.94 | \$0.00 | \$757.00 |
| \$262.61 | \$463.98 | \$0.00 | \$726.59 |

Total Expected QALYs = 15.0816

| Well | Illness | Dead | Total |
|--------|---------|--------|--------|
| 1.0000 | 0.0000 | 0.0000 | 1.0000 |
| 0.8058 | 0.0728 | 0.0000 | 0.8786 |
| 0.6918 | 0.1046 | 0.0000 | 0.7964 |
| 0.6184 | 0.1164 | 0.0000 | 0.7348 |
| 0.5661 | 0.1185 | 0.0000 | 0.6846 |
| 0.5252 | 0.1160 | 0.0000 | 0.6412 |

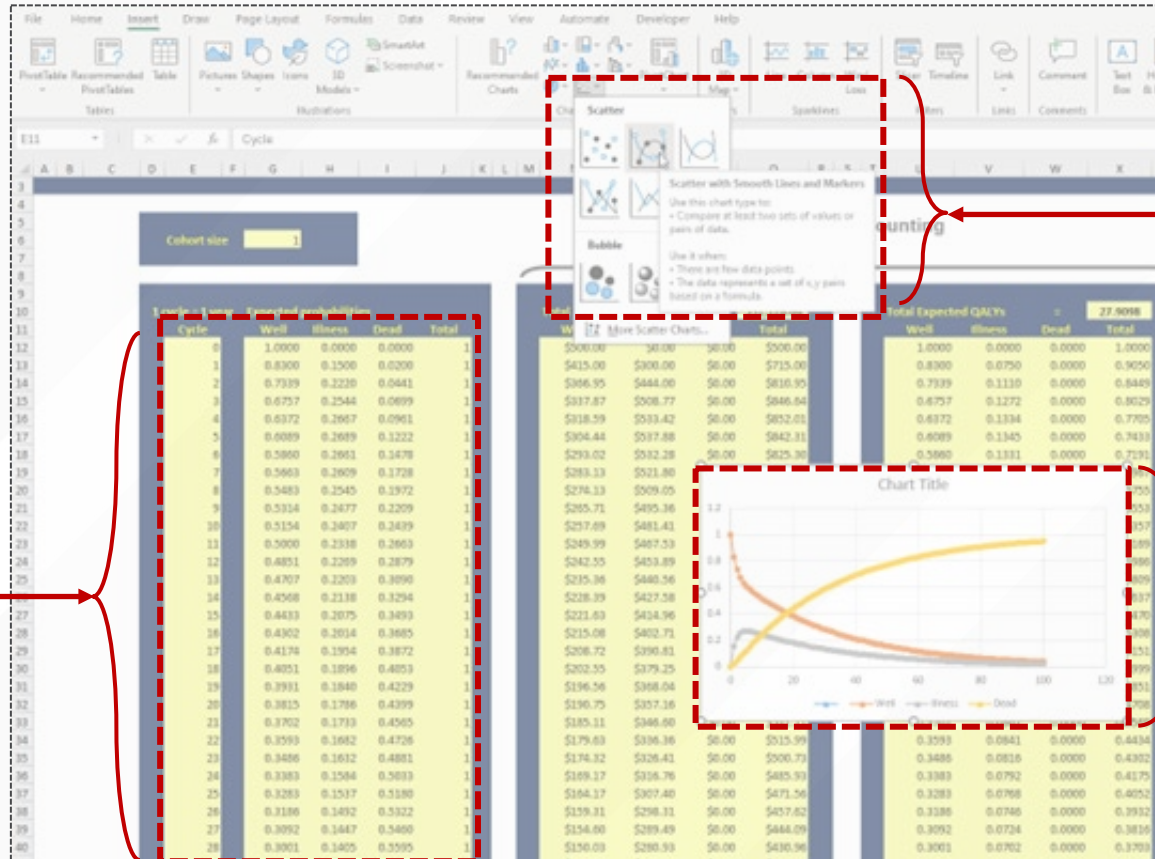

Expected costs at cycle 1 with discounting is
 $\$402.91 = (0.83 * \$500) / (1 + 0.03)^1$

$$V_0 = \frac{V_t}{(1+r)^t}$$

MARKOV MODEL RESULTS (1)

| <u>Strategy</u> | <u>Total Cost</u> | <u>Total QALYs</u> | <u>Incremental Costs</u> | <u>Incremental QALYs</u> | <u>ICER</u> |
|---------------------|-------------------|--------------------|--------------------------|--------------------------|-------------|
| Without Discounting | \$31,128.64 | 27.9098 | \$14,890.09 | 12.8282 | \$1,160.73 |
| With Discounting | \$16,238.55 | 15.0816 | | | |

MARKOV MODEL RESULTS (2)

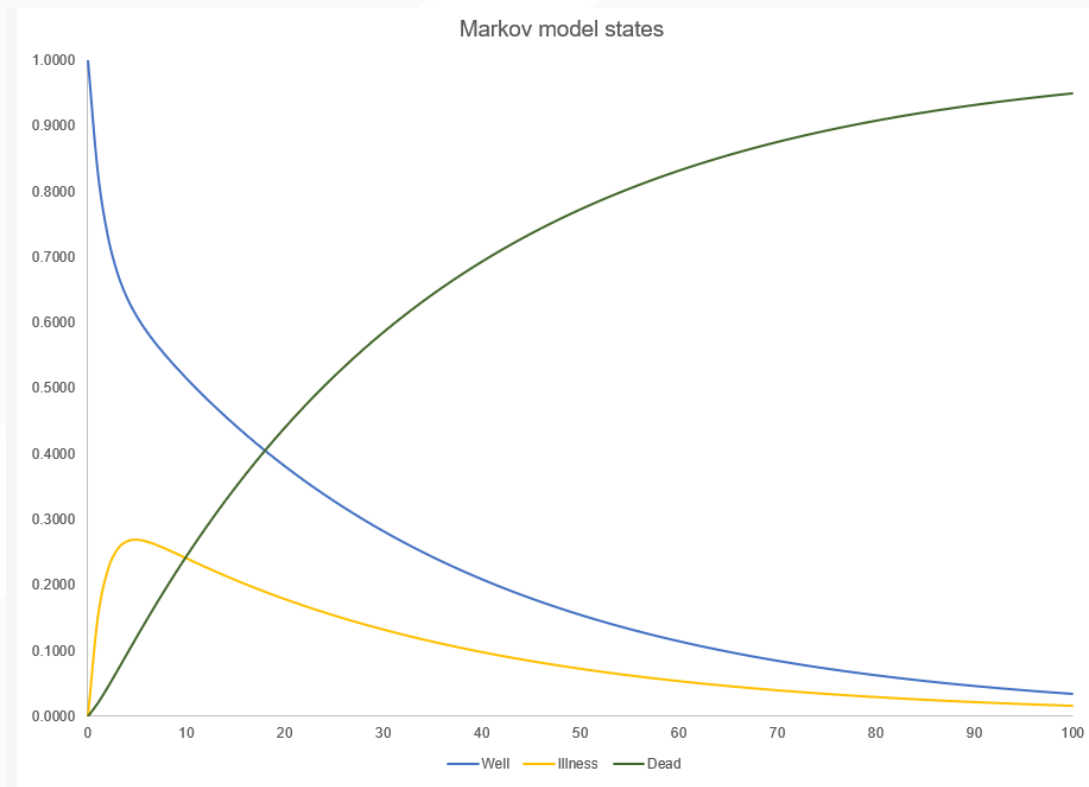

Step 1: Select the data from cycle 0 to 100

Step 2: Insert a chart using the X-Y scatter and the Scatter with Smooth Lines and Markers

Step 3: A chart will appear; make changes to match the figure
