VA HEALTH CARE Defining EXCELLENCE in the 21st Century

PREFACE

The VA Evidence-based Synthesis Program (ESP) was established in 2007 to provide timely and accurate syntheses of targeted healthcare topics of particular importance to clinicians, managers, and policymakers as they work to improve the health and healthcare of Veterans. QUERI provides funding for four ESP Centers, and each Center has an active University affiliation. Center Directors are recognized leaders in the field of evidence synthesis with close ties to the AHRQ Evidence-based Practice Centers. The ESP is governed by a Steering Committee comprised of participants from VHA Policy, Program, and Operations Offices, VISN leadership, field-based investigators, and others as designated appropriate by QUERI/HSR&D.

The ESP Centers generate evidence syntheses on important clinical practice topics. These reports help:

- Develop clinical policies informed by evidence;
- Implement effective services to improve patient outcomes and to support VA clinical practice guidelines and performance measures; and
- Set the direction for future research to address gaps in clinical knowledge.

The ESP disseminates these reports throughout VA and in the published literature; some evidence syntheses have informed the clinical guidelines of large professional organizations.

The ESP Coordinating Center (ESP CC), located in Portland, Oregon, was created in 2009 to expand the capacity of QUERI/HSR&D and is charged with oversight of national ESP program operations, program development and evaluation, and dissemination efforts. The ESP CC establishes standard operating procedures for the production of evidence synthesis reports; facilitates a national topic nomination, prioritization, and selection process; manages the research portfolio of each Center; facilitates editorial review processes; ensures methodological consistency and quality of products; produces “rapid response evidence briefs” at the request of VHA senior leadership; collaborates with HSR&D Center for Information Dissemination and Education Resources (CIDER) to develop a national dissemination strategy for all ESP products; and interfaces with stakeholders to effectively engage the program.

Comments on this evidence report are welcome and can be sent to Nicole Floyd, ESP CC Program Manager, at Nicole.Floyd@va.gov.

EXECUTIVE SUMMARY

INTRODUCTION

Non-adherence to medication is a serious problem in the United States (US). It is associated with increased emergency department visits and hospitalizations, higher costs of care, and greater mortality. For patients with serious mental illness, including schizophrenia and other psychotic spectrum disorders, bipolar disorder, and posttraumatic stress disorder (PTSD), adherence to psychopharmacological and/or non-psychopharmacological medications is an important concern.

There are a wide range of interventions for medication adherence. Interventions that target patients include psychosocial and behavioral interventions, including cognitive behavioral therapy (CBT) and Motivational Interviewing (MI), shared decision-making, customized adherence enhancement (CAE), Adherence and Compliance Therapies, and interventions involving family members. Other interventions target providers, such as provider education and training in MI. Interventions at the organization level may involve system-level interventions, such as financial incentives or reducing economic barriers through cost sharing; blister packaging for improving patient recall and tracking; and care coordination. Other interventions implemented at the organizational level include information and communication technology, such as electronic monitoring (e-monitoring), refill reminders via telephone or short message service (SMS); or other strategies, A recent review of interventions for medication adherence in patients with chronic illness found that educational interventions and case management were consistent in improving adherence across different clinical conditions, as were clinical reminders, pharmacist-led multicomponent approaches, and reducing out of pocket expenses for patients. This review examined interventions for medication adherence in patients with depression, but did not include other serious mental illnesses.

The goal of this report is to synthesize evidence examining the effectiveness of interventions to improve medication adherence in patients with psychotic spectrum disorders, bipolar disorder, and PTSD; the effect of these interventions on patient outcomes; and the related costs and any associated intervention specific harms. The key questions used to guide our report are:

KQ1. In adults with psychotic spectrum disorders:

a. What are the effects of medication adherence interventions on ***psychopharmacological*** adherence?
b. What are the effects of medication adherence interventions on *long-acting injectable (depot)* ***psychopharmacological*** adherence?
c. What are the effects of medication adherence interventions on ***non-psychopharmacological*** adherence?
d. What are the effects of these interventions on patient outcomes?
e. What are the harms and costs related to these interventions?

KQ2. In adults with bipolar disorder:

a. What are the effects of medication adherence interventions on ***psychopharmacological*** adherence?

b. What are the effects of medication adherence interventions on *long-acting injectable (depot)* ***psychopharmacological*** adherence?
c. What are the effects of medication adherence interventions on ***non-psychopharmacological*** adherence?
d. What are the effects of these interventions on patient outcomes?
e. What are the harms and costs related to these interventions?

KQ3. In adults with posttraumatic stress disorder (PTSD):

a. What are the effects of medication adherence interventions on ***psychopharmacological*** adherence?
b. What are the effects of medication adherence interventions on ***non-psychopharmacological*** adherence?
c. What are the effects of these interventions on patient outcomes?
d. What are the harms and costs related to these interventions?

METHODS

Data Sources and Searches

To identify relevant studies, we searched MEDLINE®, PubMed, PsycINFO©, Embase®, CINAHL©, and the Cochrane Library (Ovid EBM Reviews: Cochrane Central Register of Controlled Trials, Cochrane Database of Systematic Reviews, Database of Abstracts of Reviews of Effects, Health Technology Assessment, and NHS Economic Evaluation Database) from database inception through January 2015. We also searched ClinicalTrials.gov, the World Health Organization's International Clinical Trials Registry Platform (ICTRP), ISRCTN Registry, Conference Papers Index, and Dissertations & Theses Global, and searched the bibliographies of included studies for additional relevant citations.

Study Selection

Criteria for population, interventions, comparators, outcomes, timing, and setting (PICOTS) were developed in collaboration with our stakeholders and Technical Expert Panel. We included only studies with adult populations in general mental health settings (both inpatient and outpatient) that reported both an objective measure of adherence or validated subjective measure of adherence and a patient outcome measure. Studies conducted in forensic settings with incarcerated participants were excluded due to limited applicability. Two independent reviewers assessed all articles for inclusion, with discrepancies resolved through discussion or consultation with a third reviewer.

Data Abstraction and Quality Assessment

One investigator abstracted data into a customized Systematic Review Data Repository (SRDR) database, which was then reviewed for accuracy by a second investigator. Study quality was dual rated using risk of bias (ROB) assessment criteria based on the guidance and tools developed for the Agency for Healthcare Research and Quality's (AHRQ) Evidence-based Practice Centers (EPC), with any disagreements resolved through discussion or a third reviewer.

Data Synthesis and Analysis

We qualitatively synthesized the literature for each key question/clinical population. We compiled evidence tables of study characteristics, and analyzed individual study findings to draw conclusions. We assessed the overall strength of evidence for outcomes using a method developed for AHRQ's EPCs.

RESULTS

Results of Literature Search

From 7,944 titles and abstracts we identified 152 potentially relevant studies. After full-text review, we excluded 127 studies for a total of 24 included studies from 25 publications. Of the 518 clinical trial protocols identified by our search of trial registry websites, one study met inclusion criteria; however, this study and all data reported on ClinicalTrials.gov are represented in an included publication. We identified 21 articles (20 primary studies) for Key Question 1, 4 primary studies for Key Question 2, and no primary studies for Key Question 3.

Summary of Results for Key Questions

Key Question 1. In adults with psychotic spectrum disorders:

a. What are the effects of medication adherence interventions on psychopharmacological adherence?

Multicomponent Behavioral Interventions: Findings of the 7 included studies are mixed, with insufficient evidence from which to draw firm conclusions. Of the 4 studies examining Compliance Therapy, an intervention described in the 1997 manual by Kemp et al, one study found improved adherence at one month, but no differences by 6 months follow-up; another study found significantly greater adherence up to 18 months, and the other 2 studies found no significant differences between the Compliance Therapy and control groups, and no improvement in adherence in either group. Two studies of Adherence Therapy, an intervention based on Compliance Therapy, found no benefit over comparators. The seventh multicomponent behavioral intervention compared CBT to psychoeducation, with MI in both arms, and found no difference between groups at any time point.

Interventions Involving Family Members: The 3 studies examining interventions involving family members show a generally positive effect, with low strength of evidence. Caution in interpretation and generalization is advised due to the limited number of studies, the heterogeneity among the interventions, and mixed findings. Two studies found family interventions to be more effective than usual care, and one study found no significant difference when controlling for time.

System-level Intervention: One study found that although adherence associated with a system-level intervention was better as compared to Compliance Therapy, the differences were not significant. There is insufficient evidence to determine the efficacy of system-level interventions.

Pharmacist-led Interventions: One study found no difference between a pharmacist-led intervention and usual care. There is insufficient evidence regarding the efficacy of pharmacist-led interventions.

Technology Interventions: The 4 included studies provide low strength of evidence showing a positive effect associated with technology interventions. Two RCTs compared e-monitoring using smart pill containers/dispensers to a variety of comparators. One study, which examined e-monitoring both as an intervention and a measure of adherence, reported a significant effect of the e-monitoring intervention as assessed by pill counts and no effect as assessed by e-monitoring; a second study found adherence in the e-monitoring group to be significantly higher than both pill counts by a pharmacist and self-report. The third study compared a telephone and SMS intervention to telephone only and SMS only. Results indicated that although adherence was better in the group receiving both phone and SMS, differences were not significant, nor did adherence improve significantly for any of the groups over the duration of the study. The fourth study compared daily SMS to usual care, and found significantly better adherence in the intervention group both at the end of the active phase (3 months) and at 6-months follow-up.

Other Interventions: The 4 studies examining other interventions for medication adherence provided insufficient evidence from which to draw conclusions. One study of MI found no significant differences between the intervention group and controls. Similarly, no difference was found in adherence for a shared decision making intervention compared with usual care. Two studies examined Cognitive Adaptation Training and/or the medication adherence components of Cognitive Adaptation Training alone, with one study concluding no difference between standard Cognitive Adaptation Training and the use of only the medication adherence components (with significant benefit of both as compared with usual care), and one study that found no difference between the medication adherence components of Cognitive Adaptation Training and e-monitoring.

b. What are the effects of medication adherence interventions on long-acting injectable (depot) psychopharmacological adherence?

The 2 studies of interventions for medication adherence in patients prescribed depot antipsychotics found limited evidence of a positive effect; however, there is insufficient evidence from which to draw firm conclusions. One study of patients prescribed a depot antipsychotic included an intervention for family members, psychoeducation, and early warning sign detection. Results indicated better adherence as compared with controls up to 24 months. The second study included depot in combination with a customized multicomponent behavioral intervention, and found significantly better adherence through 25 weeks.

c. What are the effects of medication adherence interventions on non-psychopharmacological adherence?

One study examined the effect of an intervention for medication adherence on non-psychopharmacological adherence and provides insufficient evidence from which to draw conclusions. The study compared a telephone plus SMS intervention to telephone or text only. There was no significant difference between groups.

Table 1. Psychotic Spectrum Disorders: Summary of Medication Adherence Outcomes

Type of Intervention	Study Design (Combined N)	Findings	Strength of Evidence	Comments
Behavioral Multicomponent - Adherence Therapy	2 RCTs (N = 370)	Mixed findings: one study (low ROB) reported better adherence compared to usual care on the MAQ and SAI-C at 12 months, and the other (low ROB) reporting no difference from usual care on the CDR, DAI-30, and MARS at 12 weeks post-discharge.	Insufficient	Evidence from only 2 studies, with mixed findings.
Behavioral Multicomponent - Compliance Therapy	2 RCTs (N = 130) 1 NRCT (N = 70) 1 Prospective Cohort (N = 30)	Mixed findings: better MARS scores with Compliance Therapy at 1 month but not 6 months in 1 study (high ROB); better DAI and compliance scores as compared with routine management plus supportive counseling through 18 month follow in 1 study (high ROB); no benefit to Compliance Therapy up to 6 months in 2 studies (compared to nonspecific counseling and Compliance Therapy; moderate ROB).	Insufficient	Inconsistent findings among 4 studies. Risk of bias due to study design.
Other Behavioral Multicomponent	1 RCT (N = 88)	No difference between group cognitive behavioral therapy (CBT) plus MI and group psychoeducation plus MI (moderate ROB).	Insufficient	Evidence from only one study.
Depot plus Behavioral Multicomponent	1 Trial (randomization unclear) (N = 57) 1 Prospective Cohort (N = 30)	Findings indicated improved adherence related to the use of depot antipsychotic injections plus a behavioral multicomponent intervention (compared to usual care or no comparator) as measured by injection visits up to one year, and injection visits, TRQ, Morisky scale, DAI, and AMQ up to 25 weeks (moderate ROB).	Insufficient	Heterogeneity among interventions; risk of bias due to study design.
Family Intervention	3 RCTs (N = 449)	Better adherence with family interventions as measured by clinician rating/blood plasma and pharmacy records/family-report as compared to usual care in 2 studies (moderate ROB). No difference when controlling for time in a 3rd study examining a culturally modified family intervention as compared to the standard family intervention and monthly sessions (moderate ROB).	Low	Heterogeneity among interventions.
System-level Intervention	1 NRCT (N = 70)	Nonsignificant trend towards better adherence for the system-level intervention, compared with Compliance Therapy (moderate ROB).	Insufficient	Evidence from only one study.
Pharmacist-led	1 Prospective Cohort w/post hoc comparison (N = 30)	No significant difference over time or between groups (high ROB).	Insufficient	Evidence from only one study; potential risk of bias due to study design flaws.
Technology Interventions	4 RCTs (N = 434)	Mixed findings on e-monitoring/MEMS: better adherence in one study as compared to pill counts and self-reported adherence (high ROB), conflicting results in 1 study as compared to a pharmacy based intervention and usual care (low ROB). Telephone plus SMS resulted in nonsignificant adherence improvement vs telephone or SMS alone (moderate ROB); SMS alone resulted in significantly better adherence than usual care (moderate ROB).	Low	Mixed findings and heterogeneous interventions.

Type of Intervention	Study Design (Combined N)	Findings	Strength of Evidence	Comments
Motivational Interviewing (MI)	1 RCT (N = 114)	One study found no benefit to MI over usual care as measured by the MAQ or DAI (low ROB).	Insufficient	Evidence from only one study
Cognitive Adaptation Training (CAT)	2 RCTs (N = 240)	One study found that both CAT and Pharm-CAT resulted in better adherence than usual care, with no difference between the 2 (moderate ROB). The second study comparing Pharm-CAT to e-monitoring reported mixed results (low ROB).	Insufficient	Evidence from 2 studies that used different comparators.
Shared Decision Making	1 RCT (N = 107)	One study found no benefit to a shared decision making over usual care as measured by the MARS and plasma levels (high ROB).	Insufficient	Evidence from only one single study.

Note. Studies comparing interventions may be accounted for more than once.
Abbreviations: AMQ = Attitude towards Medication Questionnaire; CAT = Cognitive Adaptation Training; CBT = Cognitive behavioral therapy; CDR = Concentration to Dose Ratio; DAI = Drug Attitude Inventory; e-Monitoring = Electronic monitoring; MAQ = Medication Adherence Questionnaire; MARS = Medication Adherence Rating Scale; MEMS = Medication Event Monitoring System; MI = Motivational Interviewing; NRCT = Non-randomized controlled trial; ROB = Risk of bias; SAI-C = Schedule for the Assessment of Insight - C; SMS = Short message service; TRQ = Tablet Routine Questionnaire.

d. What are the effects of these interventions on patient outcomes?

Positive and Negative Symptom Severity: Findings related to positive and negative symptom severity were mixed, and insufficient from which to draw conclusions. Four studies evaluated the effect of interventions for medication adherence in patients along the psychotic spectrum on positive and negative symptoms. One study of an intervention involving family members resulted in a significant improvement in positive and negative symptoms. Another study examining SMS reminder messages resulted in significantly fewer negative symptoms. No other significant differences were found.

Overall Symptom Severity: Findings related to overall symptom severity were mixed and insufficient from which to form conclusions. Of the 17 studies examining overall symptom severity, 4 of 9 studies reported better total symptom severity as measured by the Positive and Negative Syndrome Scale (PANSS), 2 of 8 studies reported better score on the Brief Psychiatric Rating Scale (BPRS), and 2 of 3 studies reported better Clinical Global Impression scale (CGI) scores associated with the intervention.

Quality of Life: Findings from the 4 studies examining quality of life generally indicated no improvement associated with medication adherence interventions; however, given the heterogeneity of the interventions and limited evidence, the evidence is insufficient to form conclusions. Of the 4 studies, one study of an intervention involving SMS reminder messages resulted in better quality of life scores at the end of the intervention (3 months) but not at the 6-months follow-up.

Functional Impairment: Findings from the 10 studies examining functional impairment are mixed, and insufficient from which to form conclusions. Two studies found a positive effect on improving functional impairment associated with interventions involving family members, and functional impairment was improved in participants prescribed depot injections along with CAE. One of 3 studies examining Compliance Therapy reported greater functional improvement associated with the intervention, and one of 2 studies examining Cognitive Adaptation Training reported higher functioning associated with both standard Cognitive Adaptation Training and the use of only the medication adherence components, as compared to usual care at 3 and 6 months, with no difference thereafter.

Time to First Readmission/Hospitalization: Findings from the 10 studies examining time to first readmission or hospitalization are mixed and provide insufficient evidence from which to draw conclusions. Three studies examining interventions involving family members showed a positive effect of the intervention on hospital admissions and/or time to readmission or hospitalization. A system-level intervention resulted in a longer time to readmission as compared with Compliance Therapy, with 2 other studies also finding no effect of Compliance Therapy on readmission/hospitalization.

Time Spent in the Hospital: Three studies examined time spent in the hospital, and the evidence is insufficient from which to draw conclusions. Findings were mixed, with only one study of a family intervention reporting a shorter stay associated with the intervention.

Time to Relapse: The 2 studies examining time to relapse reported better outcomes associated with the intervention, with longer time to relapse associated with a family intervention, and both

standard Cognitive Adaptation Training and the use of only the medication adherence components, as compared to usual care.

Side Effects: One study compared a system-level intervention to Compliance Therapy and examined side effects related to psychopharmacological interventions, and found fewer side effects associated with Compliance Therapy.

e. What are the harms and costs related to these interventions?

Two studies examined costs associated with interventions to improve medication adherence in patients along the psychotic spectrum. One study found no difference between Compliance Therapy and routine management with supportive counseling, and the second study found a higher average cost per patient associated with the adherence components of Cognitive Adaptation Training as compared to e-monitoring.

Key Question 2. In adults with bipolar disorder:

*a. What are the effects of medication adherence interventions on **psychopharmacological** adherence?*

The 4 studies meeting inclusion criteria for Key Question 2 provide limited evidence regarding the effectiveness of interventions for medication adherence in patients with bipolar disorder. Three of the 4 studies found a positive effect on psychopharmacological adherence associated with an adherence intervention, with high rates of attrition in the one study reporting no effect. Despite evidence suggesting a generally positive effect, the strength of the evidence is insufficient due to the fact that the interventions were heterogeneous, sample sizes were small, and external validity questionable because 2 studies showing a positive effect were conducted in Iran (see Table 2).

d. What are the effects of these interventions on patient outcomes?

Depression: Findings of the 3 studies examining the effect of medication adherence interventions on depressive symptomology are mixed and provide insufficient evidence from which to draw conclusions. Of the 3 included studies, one study examining an individual psychoeducation intervention found a positive effect on depression associated with the intervention. A second study found that CAE resulted in significantly improved depression scores, but only at 6 months, while the third study showed no effect.

Mania: Findings of the 3 studies examining the effect of medication adherence interventions on mania are mixed and provide insufficient evidence from which to draw conclusions. Of the 3 included studies, 2 showed significant effects on mania-related outcomes. One study examining an individual psychoeducation intervention found a positive effect on mania symptoms associated with the intervention. A second study of CAE found no difference in mania scores at 3 months, but mania scores were significantly lower at 6 months.

Functional Impairment: Similar to results examining depression and mania, 2 of 3 studies reporting functional impairment outcomes in patients with bipolar disorder reported positive effects. One study reported a positive effect on improving functional impairment associated with a group psychoeducation intervention, and a second study (examining CAE) found no improvement between baseline and 3 months, but did report improved function at 6 months.

Single studies examined symptom severity, positive and negative affect, quality of life, and hospital readmissions. One study found no improvement associated with CAE on symptom severity at 3 months, with significant improvements by 6-months follow-up. Positive and negative affective symptoms improved significantly from baseline at both 3 and 6 months. Another study found significantly higher quality of life scores and fewer hospital readmissions over an 18-month period associated with an individual psychoeducation intervention.

No studies were identified examining the effect of medication adherence interventions on *long-acting injectable (depot) psychopharmacological* adherence (Key Question 2b), *non-psychopharmacological* adherence (Key Question 2c), or reporting harms or costs associated with the intervention (Key Question 2e).

Key Question 3. In adults with PTSD:

We identified no studies meeting inclusion criteria for Key Question 3.

Table 2. Bipolar Disorder: Summary of Medication Adherence Outcomes

Type of Intervention	Study Design (Combined N)	Findings	Strength of Evidence	Comments
Psychoeducation (individual/group)	1 RCT (N = 108) 1 NRCT (N = 45)	Both individual and group psychoeducation resulted in better medication adherence than pharmacotherapy alone or pharmacotherapy with standard psychotherapy (moderate ROB).	Insufficient	Evidence from only 2 studies, external validity due to setting
Psychoeducation plus problem solving	1 RCT (N = 164)	There was no improvement in medication adherence associated with the intervention as compared to usual care (moderate ROB).	Insufficient	Evidence from only one study. Only 75% of the intervention group and 81% of the control group participated in baseline plus one other assessment, and only 49% of the intervention group participated in most or all of the group sessions, with 37% never participating.
Customized Behavioral Multicomponent (psychoeducation, substance use/modified MET, provider communication, medication management)	1 Prospective Cohort (N = 43)	Customized adherence enhancement (CAE) was associated with better adherence and attitudes towards medication at 3 and 6 months (moderate ROB).	Insufficient	Evidence from only one study; risk of bias due to study design.

Abbreviations: CAE = Customized adherence enhancement; MET = Motivational Enhancement Therapy; NRCT = Non-randomized controlled trial; RCT = Randomized controlled trial; ROB = Risk of bias.

DISCUSSION

We found 24 studies in 25 publications with the potential to inform policies and practices related to medication adherence in patients with severe mental illness in the VHA. Twenty studies (reported in 21 articles) examined patients with psychotic spectrum disorders, and 4 studies were in patients with bipolar disorder. We identified no studies examining patients with PTSD. The interventions designed to improve medication adherence across Key Questions 1 and 2 differed widely, with very few studies evaluating the same specific interventions. Despite a variety of interventions designed to increase psychopharmacological adherence, study limitations (*eg*, differences in population and setting, heterogeneity among studies, a wide range of comparators, and the challenge of evaluating complex interventions), as well as concerns regarding applicability to the VHA, preclude us from drawing strong conclusions.

There is limited evidence that the involvement of family members, the use of technology (*eg*, e-monitoring, SMS, telephone), and the combination of a depot antipsychotic and another intervention may be effective in improving adherence. However, these findings must be interpreted with caution, given the heterogeneity among interventions, the difficulty in determining the contribution of the depot antipsychotic versus the adherence intervention, the methodological limitations and the lack of consistent replication of any specific intervention. With the exception of interventions involving technology and system-level interventions, many interventions include behavioral or other techniques (*eg*, MI) that are flexible and designed to adapt to different settings and patients. While these techniques have been found effective in the treatment of other mental health conditions (*eg*, anxiety, depression, substance abuse), additional research of standardized interventions designed to improve medication adherence is needed to replicate findings across settings and populations in order to better understand their effect on adherence and patient outcomes. Similarly, many of the included studies compare interventions for medication adherence to usual care, rather than an active comparator. Given the population and the nature of mental illness, it is possible that the lack of active controls may result in more frequent provider interaction for the intervention group than for those receiving usual care. More frequent contact alone has the potential to result in improved outcomes, and it is impossible to ascertain whether any effect was due to the intervention or to increased attention. Finally, sampling bias may exist related to baseline differences in the adherence of individuals selected to enroll in studies examining interventions designed to improve medication adherence and those who do not – particularly in studies examining long-acting injectable depot antipsychotics.

An additional challenge in accurately assessing the body of research examining medication adherence is the wide range of methods used to assess adherence. We limited our inclusion to studies that assessed adherence using an objective measure such as blood plasma concentration levels, pill counts, e-monitoring/MEMS caps, or using a validated adherence scale.[1] For studies using multiple adherence measures, it was not uncommon for the determination of adherence to be incongruent, leading to questions related to the validity of commonly used and validated objective and subjective measures.

There is a paucity of research examining the effect of medication adherence interventions on non-psychopharmacological interventions. Given the risk of comorbid health conditions (*eg*, diabetes, hypertension) in persons with serious mental illness, future research should evaluate the impact of adherence interventions aimed at prevalent comorbid non-psychiatric conditions.

Furthermore, we identified no studies evaluating the potential harms that may result from these interventions. Despite the fact that the potential for harm appears to be low as compared to the risks associated with both the use of, and non-adherence to, prescribed medication, research documenting relative risk is warranted. Similarly, very few studies evaluated differential effects in subpopulations. It is important to understand whether both the benefits and potential harms differ by subgroup or clinical subpopulation and whether one type of intervention may be more effective than others for a given population or setting.

We identified no studies examining interventions to improve medication adherence in patients with PTSD. Although trauma processing therapies are often the first line of treatment for patients with PTSD, pharmacological interventions are commonly used as adjunctive therapy to alleviate associated symptoms and to treat comorbid conditions. There is limited evidence to suggest that adherence to medication is poor in Veterans with PTSD who are taking medication. Thus, future research is warranted to determine whether improvements in adherence in this population can be achieved through the use of interventions, or by adapting interventions developed for other patient populations.

Conclusions

Findings from the studies examining interventions to improve medication adherence in patients with psychotic spectrum disorders are mixed and evaluate a wide range of heterogeneous interventions. Sample sizes were generally small, studies often lacked an active comparison group, and there was wide variation in how adherence was measured among studies. There is limited evidence to support improved adherence associated with interventions involving family members, those involving technology, and those combining a depot antipsychotics with another intervention. Findings were mixed regarding the effectiveness of multicomponent behavioral interventions, with no support for Adherence or Compliance Therapies. In addition, no clear evidence exists to support conclusions regarding the effect of medication adherence interventions on patient outcomes. Very few studies examined interventions for medication adherence in patients with bipolar disorder, and while in general there appears to be a positive effect of these interventions on adherence in this population, interventions were heterogeneous and more research is needed. No studies were found examining PTSD populations. For all populations, methodologically rigorous replication studies of standardized treatments using objective or validated subjective measures of adherence are needed to confirm preliminary results, as is research examining the costs and potential harms associated with the wide array of interventions designed to improve medication adherence.

ABBREVIATIONS TABLE

Abbreviation	Term
AHRQ	Agency for Healthcare Research and Quality
AMQ	Attitude towards Medication Questionnaire
BPRS	Brief Psychiatric Rating Scale
BPRS–E	Brief Psychiatric Rating Scale – Expanded
CAE	Customized Adherence Enhancement
CAT	Cognitive Adaptation Training
CBT	Cognitive Behavioral Therapy
CDR	Concentration to Dose Ratio
CGI	Clinical Global Impression

CGI-BP	Clinical Global Impression – Bipolar scale
CGI-SGH	Clinical Global Impression – Schizophrenia scale
CI	Confidence Interval
DAI	Drug Attitude Inventory
e-monitoring	electronic-monitoring
EPC	Evidence-based Practice Centers
EQ-5D	EuroQoL
ES	Effect size

GAS	Global Assessment Scale
HAM-D	Hamilton Depression Rating Scale
LEE	Level of Expressed Emotion
LGP	Life Goals Program
M	Mean
MAQ	Medication Adherence Questionnaire
MARS	Medication Adherence Rating Scale
MDN	Median
MEMS	Medication Event Monitoring System
MET	Motivational Enhancement Therapy
MI	Motivational Interviewing
MM	Med-eMonitor
NA	Not applicable
NRCT	Non-randomized controlled trial
NS	Not significant
PANSS	Positive and Negative Syndrome Scale
PICOTS	Population, interventions, comparators, outcomes, timing, and setting
PTSD	Posttraumatic stress disorder
QLF	Quality of Life Scale
RCT	Randomized controlled trial
ROB	Risk of Bias
SAI	Schedule for Assessment of Insight
SAI-C	Schedule for the Assessment of Insight - C
SAI-E	Schedule for Assessment of Insight- Expanded
SD	Standard deviation
SE	Standard error
SF-36	Short Form Health Survey
SMS	Short message service
SOFAS	Social and Occupational Functioning Scale
SRDR	Systematic Review Data Repository
SWN	Subjective Well-being on Neuroleptic Treatment Scale
TIPS	Telephone Intervention Problem Solving for Schizophrenia
TRQ	Tablet Routine Questionnaire
VA	Veterans Affairs
VHA	Veterans Health Administration
WHOQOL-BREF	World Health Organization Quality of Life instrument – Abbreviated version
WSRT	Wilcoxon signed-rank test
YMRS	Young Mania Rating Scale

EVIDENCE REPORT

INTRODUCTION

Non-adherence to medication is a serious problem in the United States (US). It is associated with increased emergency department visits and hospitalizations,[2-7] higher costs of care,[2,6,7] and greater mortality.[8,9] For patients with serious mental illness, including schizophrenia and other psychotic spectrum disorders, bipolar disorder, and posttraumatic stress disorder (PTSD), adherence to psychopharmacological and/or non-psychopharmacological medications is an important concern. While some similarities exist, in general, these 3 populations are largely distinct in the factors associated with medication non-adherence and related outcomes, with some overlap in the interventions used to increase adherence.

For individuals with schizophrenia and other psychotic spectrum disorders, antipsychotic medications are a primary focus of treatment.[10] Among people with schizophrenia, adherence to antipsychotic medication is estimated to be between roughly 25%[11,12] to 50%[13]; in a study of patients with schizophrenia or schizoaffective disorder in the Veterans Affairs (VA) system, an adherence rate of 60% was reported.[14] Wide variation exists in reported adherence rates, and largely depend on the length of time examined and the method used to measure adherence.[15] Factors related to non-adherence in individuals with psychotic spectrum disorders may include patient-level factors such as lack of awareness or insight into the illness, negative attitudes towards medication,[15,16] comorbid substance use, and cognitive impairment; demographic factors such as younger age, male gender, and lower socioeconomic status; relationship factors such as a poor therapeutic alliance and poor social support; and system-level factors such as co-pays, medication supervision, and access to mental healthcare providers.[16] In addition to poor adherence to antipsychotic medications, individuals with schizophrenia and other psychotic spectrum disorders may be prone to poor adherence to medications prescribed for comorbid conditions, with one study reporting similar adherence rates for psychopharmacologic and non-psychopharmacologic therapies,[17] and another study using VA data reporting a higher rate of non-adherence to oral hypoglycemic medications among Veterans with schizophrenia than without.[18]

Similar to individuals along the psychotic spectrum, psychopharmacological medications (*eg*, antipsychotics and mood stabilizers) are the first line of treatment for patients with bipolar disorder,[19] with reported rates of adherence between 30%-57%.[20-22] Studies conducted in VA settings reported an adherence rate of 51.9%.[16,23] While many of the factors associated with non-adherence to antipsychotic medications – such as lack of insight into illness, comorbid substance use, cognitive function, and a poor therapeutic alliance – are similar to those found in individuals with psychotic spectrum disorders, other factors are more specific to patients with bipolar disorder, such as being unmarried, female, and homeless, having an external locus of control (*eg*, events are controlled by external factors rather than their own actions), having more suicide attempts, and receiving less-intensive psychopharmacologic treatments.[23]

Unlike patients with psychotic spectrum disorders or bipolar disorder, for individuals with PTSD, trauma processing therapy is often the first line of treatment.[24] Pharmacologic treatment is also used to treat PTSD, including serotonergic antidepressants, adrenergic receptor antagonists such as prazosin, second-generation antipsychotics, and anticonvulsants.[24] For

patients with PTSD, in addition to pharmacologic treatment for PTSD symptoms, non-adherence to medications for comorbid disorders may be a particular concern, with studies reporting higher rates of non-adherence to medications for cardiovascular disease.[25,26] While few studies examine medication adherence rates in patients with PTSD, one study of individuals discharged from a VA PTSD treatment program reported that 66% were non-adherent during the 12 months following discharge. A second study of Veterans stated that 12% of participants reported not taking their medication, 41% reported forgetting to take their medication, and 24% reported skipping medication.[26,27]

Current measures of medication adherence vary widely, with a broad range of inherent limitations, often related to validity or cost. Objective measures of adherence include observed intake, pill counts, electronic monitoring (e-monitoring), administrative pharmacy claims, and blood plasma concentration levels; subjective measures include patient report, self-reported scales, patient diaries, reports by caregivers or case managers, and clinician's views on adherence based on therapeutic response.[28-30]

Due to the extensiveness of medication non-adherence and its severe health consequences for patients with severe mental illness, many interventions have been developed to try to combat this problem. Interventions for medication adherence include patient-level interventions such as Adherence and Compliance Therapies; adherence skills trainings; psychosocial and behavioral interventions, including cognitive behavioral therapy (CBT) and Motivational Interviewing (MI), shared decision-making, customized adherence enhancement (CAE), and interventions involving family members. Provider-level interventions include provider education and training in MI. System-level interventions include financial incentives; methods related to information and communication technology (*eg*, phone follow-up, electronic reminder systems, e-Health interventions, refill reminders); reducing economic barriers (*eg*, cost-sharing, reducing co-pays); blister or unit dose packaging; case management or care coordination; and simplified dosing or dosing frequency strategies, including long-acting injectables. A recent review of interventions for medication adherence in patients with chronic illness found that educational interventions and case management were consistent in improving adherence across different clinical conditions, as were clinical reminders, pharmacist-led multicomponent approaches, and reducing out of pocket expenses for patients.[31] While this review did examine interventions for medication adherence in patients with depression, it did not include other serious mental illnesses.

The goal of this evidence report is to summarize the current evidence examining the effectiveness of interventions to improve medication adherence in patients with psychotic spectrum disorders, bipolar disorder, and PTSD, the effect of these interventions on patient outcomes, as well as the related costs and any associated intervention specific harms. As the Veterans Health Administration (VHA) continues to strive to provide high quality care, a better understanding of adherence interventions for these distinct populations will help to aid the VA in determining the programs and policies most appropriate for improving Veterans' health.

METHODS

TOPIC DEVELOPMENT

This topic was submitted to the ESP Coordinating Center by Anthony Morreale, PharmD, MBA, BCPS, FASHP, Assistant Chief Consultant for Clinical Pharmacy Services and Health Services Research, in the VA Office of Pharmacy Benefits Management Services. We further refined the scope and key questions for this topic through a preliminary search of peer-reviewed literature, and in concert with internal partners and investigators, Dr. Morreale, and a Technical Expert Panel comprised of both VA and non-VA experts (Appendix A). The key questions for the review are as follows:

KQ1. In adults with psychotic spectrum disorders:

a. What are the effects of medication adherence interventions on ***psychopharmacological*** adherence?
b. What are the effects of medication adherence interventions on *long-acting injectable (depot)* ***psychopharmacological*** adherence?
c. What are the effects of medication adherence interventions on ***non-psychopharmacological*** adherence?
d. What are the effects of these interventions on patient outcomes?
e. What are the harms and costs related to these interventions?

KQ2. In adults with bipolar disorder:

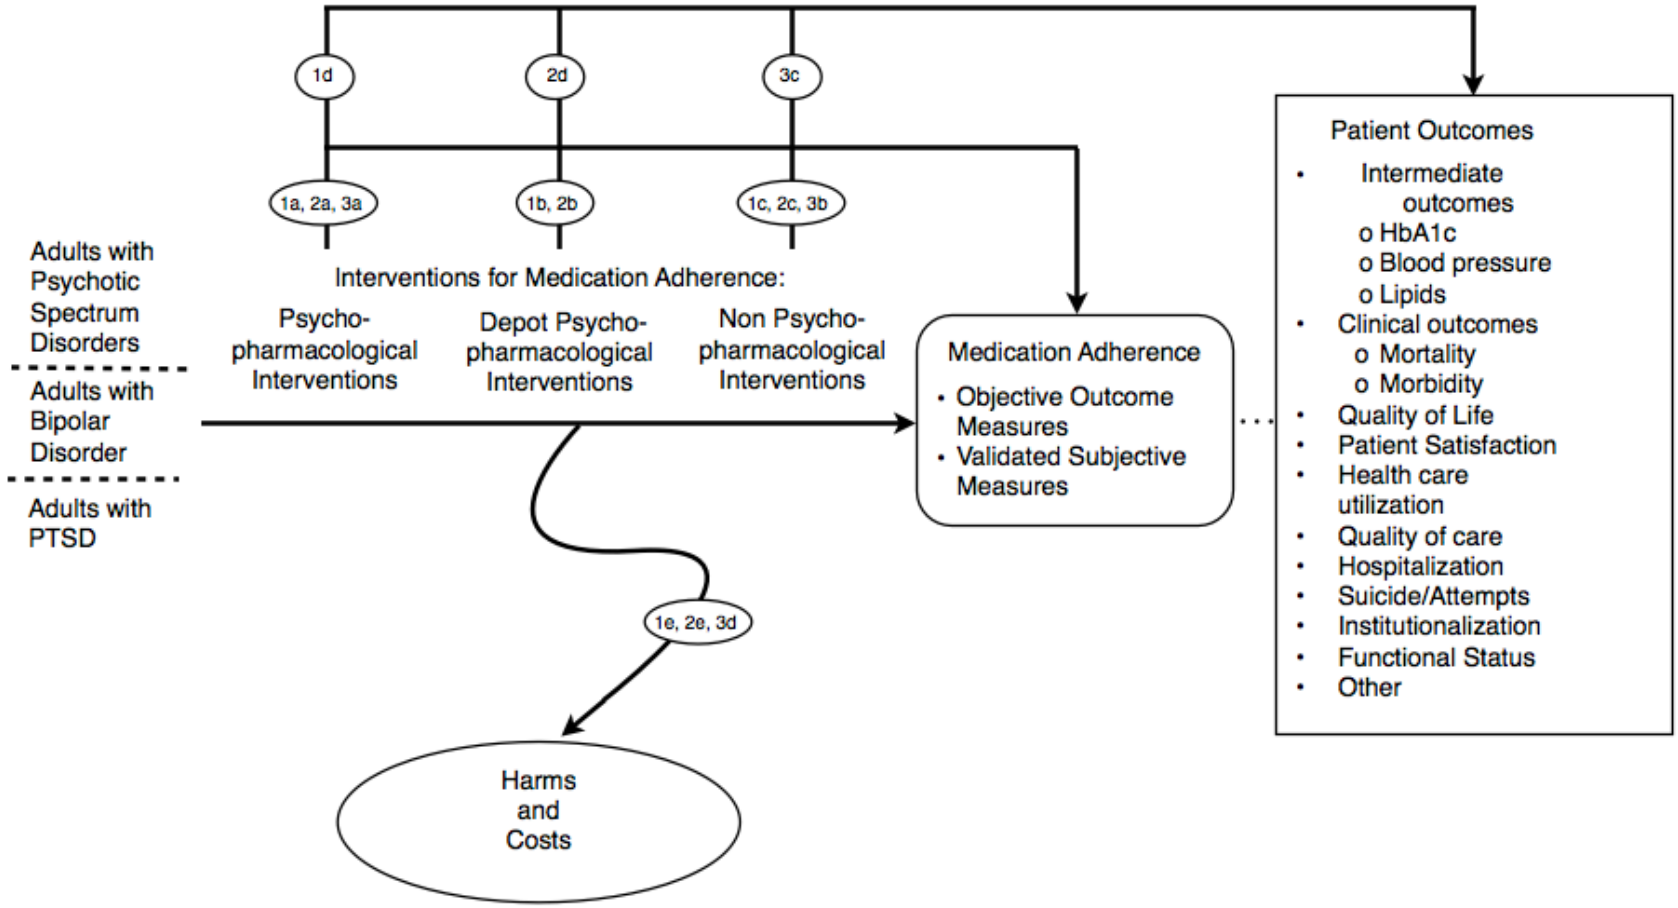
a. What are the effects of medication adherence interventions on ***psychopharmacological*** adherence?
b. What are the effects of medication adherence interventions on *long-acting injectable (depot)* ***psychopharmacological*** adherence?
c. What are the effects of medication adherence interventions on ***non-psychopharmacological*** adherence?
d. What are the effects of these interventions on patient outcomes?
e. What are the harms and costs related to these interventions?

KQ3. In adults with posttraumatic stress disorder (PTSD):

a. What are the effects of medication adherence interventions on ***psychopharmacological*** adherence?
b. What are the effects of medication adherence interventions on ***non-psychopharmacological*** adherence?
c. What are the effects of these interventions on patient outcomes?
d. What are the harms and costs related to these interventions?

Our approach was guided by the analytic framework shown in Figure 1.

Figure 1. Analytic Framework: Interventions for Medication Adherence in Adults with Psychotic Spectrum Disorders, Bipolar Disorder, and Posttraumatic Stress Disorder



Abbreviations: HbA1c = Glycated hemoglobin; PTSD = Posttraumatic Stress Disorder.

SEARCH STRATEGY

A search strategy was developed in consultation with a research librarian, and was peer reviewed by a second research librarian using the instrument for Peer Review of Search Strategies (PRESS).[32,33] We conducted a primary review of the literature by systematically searching, reviewing, and analyzing the scientific evidence as it pertains to the key questions from database inception to January 27, 2015. To identify relevant articles, we searched MEDLINE®, PubMed, PsycINFO©, Embase®, CINAHL©, and the Cochrane Library (Ovid EBM Reviews: Cochrane Central Register of Controlled Trials, Cochrane Database of Systematic Reviews, Database of Abstracts of Reviews of Effects, Health Technology Assessment, and NHS Economic Evaluation Database). In addition, we evaluated the bibliographies of included primary studies and any relevant systematic or nonsystematic reviews that were identified. To identify studies not published in peer-reviewed journals, we searched ClinicalTrials.gov, the World Health Organization's International Clinical Trials Registry Platform (ICTRP), ISRCTN Registry, Conference Papers Index, and Dissertations & Theses Global. The complete search strategy is provided in Appendix B.

STUDY SELECTION

Criteria for population, interventions, comparators, outcomes, timing, and setting (PICOTS) were developed in collaboration with our stakeholders and Technical Expert Panel, and are provided in Table 3. We included only studies with adult populations examining interventions designed to improve medication adherence in general mental health settings (both inpatient and outpatient) that reported both a patient outcome measure and an objective or validated subjective measure of adherence.[1] Studies set in forensic settings with incarcerated participants were excluded due to limited applicability (*eg*, including increased supervision, medication distribution). Eligible study designs included randomized controlled trials (RCTs) or methodologically rigorous observational studies, including before/after studies with at least 3 time points and that completed analyses that controlled for time. Using pre-specified inclusion/exclusion criteria (Appendix C), 2 independent reviewers reviewed titles and abstracts using Abstrackr[34] and agreed on a final inclusion/exclusion decision for 10% of the search yield, with the remaining 90% decided by a single reviewer. Clinical trials were reviewed for inclusion according to the same pre-specified inclusion criteria by the primary investigator. At the full-text screening stage, 2 independent reviewers assessed all articles for inclusion (Appendix D). Discordant results were resolved through discussion or consultation with a third if discrepancies could not be resolved between the first 2 reviewers. Articles meeting eligibility criteria were included for data abstraction.

Table 3. PICOTS by Key Question

Key Question	**KQ1.** In patients with psychotic spectrum disorders: a. What are the effects of medication adherence interventions on ***psychopharmacological*** adherence? b. What are the effects of medication adherence interventions on *long-acting injectable (depot)* ***psychopharmacological*** adherence? c. What are the effects of medication adherence interventions on ***non-psychopharmacological*** adherence? d. What are the effects of these interventions on patient outcomes? e. What are the harms and costs related to these interventions?	**KQ2**. In patients with bipolar disorder: a. What are the effects of medication adherence interventions on ***psychopharmacological*** adherence? b. What are the effects of medication adherence interventions on *long-acting injectable (depot)* ***psychopharmacological*** adherence? c. What are the effects of medication adherence interventions on ***non-psychopharmacological*** adherence? d. What are the effects of these interventions on patient outcomes? e. What are the harms and costs related to these interventions?	**KQ3.** In patients with posttraumatic stress disorder (PTSD): a. What are the effects of medication adherence interventions on ***psychopharmacological*** adherence? b. What are the effects of medication adherence interventions on ***non-psychopharmacological*** adherence? c. What are the effects of these interventions on patient outcomes? d. What are the harms and costs related to these interventions?
Populations	Adults with psychotic spectrum disorders	Adults with bipolar disorder	Adults with PTSD
Intervention	Studies where the primary outcomes include medication adherence, including: § Patient-level interventions specifically designed to address medication adherence, such as: Compliance or Adherence Therapies, adherence skills training, psychosocial interventions (*eg*, psychoeducation, behavioral interventions, MI, cognitive interventions), customized adherence enhancement, family-supervised treatment, shared decision-making or § Provider-level interventions specifically designed to address medication adherence, such as provider education, and training in MI or § Systems-level interventions specifically designed to address medication adherence, such as: financial incentives, information and communication technology (*eg*, follow-up by phone, electronic reminder systems), reduction of economic barriers to adherence (*eg*, reducing copayments or prescription cost, cost-sharing), blister or unit-dose packaging, augmented pharmacy services, internet-based or eHealth interventions, simplified dosing or dosing frequency strategies, long-acting injectables (depot), case management or care coordination (*eg*, assertive community treatment, nurse-facilitated enhanced-treatment)		
Comparator	· Other active interventions · No treatment · Usual care · Studies with no comparison group only if outcome data are provided for baseline and at least 2 additional time points		
Outcomes	Medication adherence: § Measured objectively (*eg*, medication container with electronic monitoring [*eg*, MEMS], pill counts, biological markers, observed intake, medication possession ratio, medication plasma level, electronic ingestible event marker) § Measured subjectively by a validated patient self-report scale or measure (*eg*, Morisky Medication Adherence Scales [MMAS-8, MMAS-4 or MAQ]). See Nguyen et al for a list of validated measures.[1]		

	Patient outcomes: § Intermediate patient outcomes (HbA1c, blood pressure, lipids), clinical outcomes (mortality, morbidity), quality of life, patient satisfaction, health care utilization, quality of care, hospitalization, suicide/attempts, institutionalization, functional status, other. Costs **Exclude:** Medication adherence not the primary outcome –OR– Patient self-report, caregiver report, case manager report, clinician's view based on therapeutic response, and other non-validated subjective outcomes.
Timing	Short- and long-term outcomes
Study Design	RCTs; Methodologically rigorous observational studies (case control/cohort studies) that adjust for important confounders, and if no comparison group exists, data must be provided for baseline and at least 2 additional time points with analyses examining the trend and controlling for time.

DATA ABSTRACTION

Data from published reports were abstracted into a customized Systematic Review Data Repository (SRDR)[35] database by one investigator (among KK, DH, KJ, AM, AL) and confirmed by a second reviewer. From each study, we abstracted the following where available: study design, objectives, setting, population characteristics (including sex, age, race/ethnicity, diagnosis), subject eligibility and exclusion criteria, number of subjects, years of enrollment, duration of follow-up, the study and comparator interventions, important co-interventions, medication/class, number of medications, medication adherence outcomes, medication adherence thresholds, clinical outcomes, implementation factors, and harms.

QUALITY ASSESSMENT

Two reviewers (among KK, DH, KJ, AM, AL, MM) independently assessed the quality of each study using the risk of bias (ROB) assessment criteria developed for a recent high-quality comparative effectiveness review examining medication adherence interventions that did not address the populations included in this report.[31] This report followed the guidance and tools developed for the Agency for Healthcare Research and Quality's (AHRQ) Evidence-based Practice Centers (EPC), and allows for the assessment of ROB for a wide range of study designs.[36,37] Disagreements were resolved through discussion with a third reviewer evaluating methodological quality if consensus could not be reached between the first 2 reviewers. Each study was given an overall summary assessment of low, medium, high, or unclear ROB (Appendices G & H):[36]

- Low ROB = We have confidence that the results represent the true treatment effect. The study reporting is adequate to judge that no major or minor sources of bias are likely to influence results.
- Medium ROB = We have some confidence that the results represent the true treatment effect. The study is susceptible to some bias, but the problems are not sufficient to invalidate the results.
- High ROB = We have low confidence that results represent the true treatment effect. The study has significant flaws that imply biases of various types that may invalidate its results; these may arise from serious errors in conduct, analysis, or reporting, large amounts of missing information, or discrepancies in reporting.
- Unclear ROB = The study is missing information, making it difficult to assess limitations and potential problems.

DATA SYNTHESIS

We summarized the primary literature by abstracting relevant data and qualitatively synthesizing the literature for each key question/clinical population. Due the heterogeneity in the literature, a meta-analysis was not performed. We constructed evidence tables outlining study characteristics, organized by key question, and analyzed individual study findings to draw conclusions.

RATING THE BODY OF EVIDENCE

We assessed the overall strength of evidence for outcomes using a method developed for AHRQ's EPCs.[38] The AHRQ EPC method considers study limitations, directness, consistency, precision,

and reporting bias to classify the strength of evidence for individual outcomes independently for randomized controlled trials and observational studies, with supplemental domains of dose-response association, plausible confounding that would decrease the observed effect, and strength of association, as well as separate guidance for applicability as follows:[39]

- High = We are very confident that the estimate of effect lies close to the true effect for this outcome. The body of evidence has few or no deficiencies. We believe that the findings are stable; in other words, another study would not change the conclusions.
- Moderate = We are moderately confident that the estimate of effect lies close to the true effect for this outcome. The body of evidence has some deficiencies. We believe that the findings are likely to be stable, but some doubt remains.
- Low = We have limited confidence that the estimate of effect lies close to the true effect for this outcome. The body of evidence has major or numerous deficiencies (or both). We believe that additional evidence is needed before concluding either that the findings are stable or that the estimate of effect is close to the true effect.
- Insufficient = We have no evidence, we are unable to estimate an effect, or we have no confidence in the estimate of effect for this outcome. No evidence is available or the body of evidence has unacceptable deficiencies, precluding reaching a conclusion

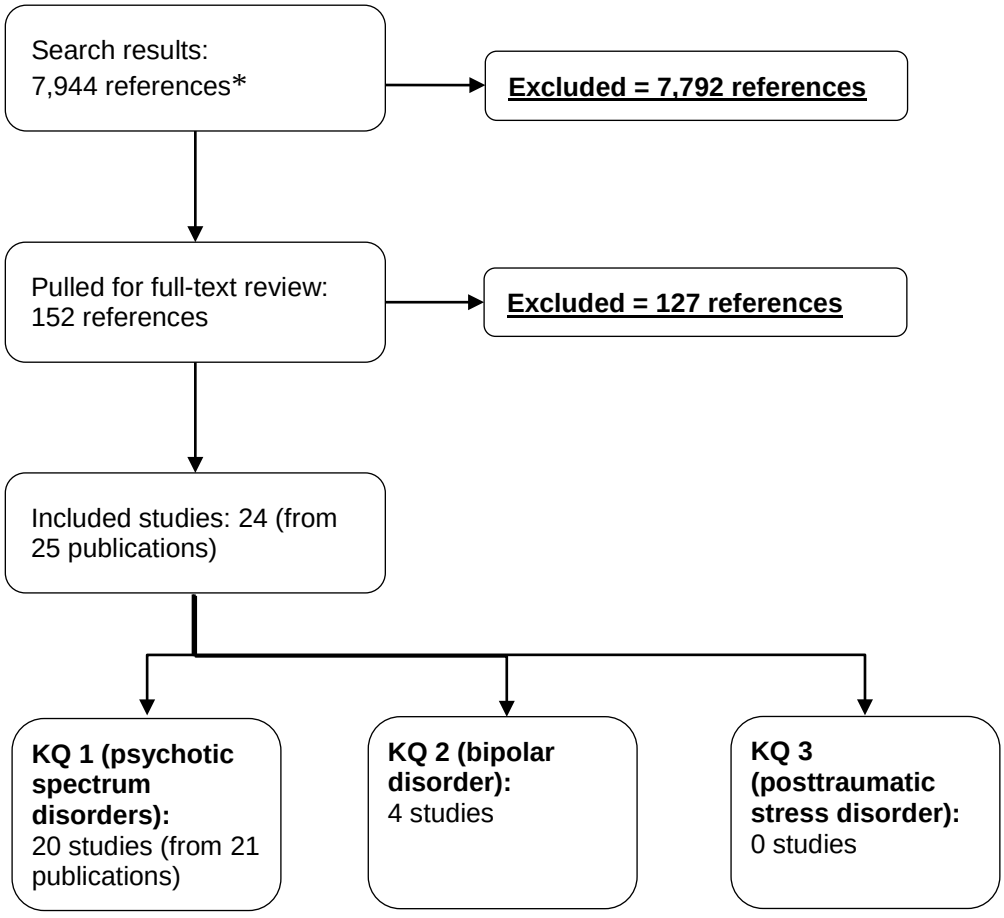
RESULTS

Our search of electronic databases, bibliographies, and other sources resulted in a total of 7,944 studies. After title and abstract review, 152 were selected for full-text review. Upon review of the full-text articles, we excluded 127 citations for a total of 24 included studies from 25 publications. Additionally, a search of the ClinicalTrials.gov online trial registry identified 518 clinical trials, and one study met inclusion criteria;[40] however, this study and all data reported on ClinicalTrials.gov are represented in an included publication.[41] We identified 21 articles (20 individual primary studies) for Key Question 1, 4 primary studies for Key Question 2, and no primary studies for Key Question 3.

LITERATURE FLOW

Figure 2 shows the citation yield from electronic database searches and other sources, numbers for exclusions at the abstract and full-text phases, and the final yield of included studies delineated by key question.

Figure 2. Literature Flow Chart



* 7,895 were identified through database searches (Appendix B), and an additional 49 were identified from the bibliographies of relevant systematic reviews and primary studies.

KEY QUESTION 1. ADULTS WITH PSYCHOTIC SPECTRUM DISORDER

We identified 21 articles meeting inclusion criteria for patients along the psychotic spectrum, with 20 independent studies reporting medication adherence outcomes, and one article[42] reporting a cost analysis of another included study.[43] Seven studies examined multicomponent behavioral interventions;[43-49] 3 studies examined interventions involving family members;[50-52] one study examined a system-level intervention;[49] one study examined a pharmacist-led intervention;[53] 4 studies examined technology interventions (Medication Event Monitoring System [MEMS], telephone, short message service [SMS]);[54-57] and 4 studies examined other interventions such as MI (1 study),[58] shared decision-making (1 study),[59] and environmental supports (2 studies).[57,60] Two studies examined the combination of depot antipsychotics and an intervention designed to increase medication adherence,[61,62] one study reported the intervention effect on non-psychopharmacologic medications,[54] and 2 studies reported outcomes related to costs.[42,57] Study details are found in Tables 4-11.

Studies were conducted in community mental health outpatient settings (12 studies) and in hospitals with inpatients (4 studies), with other interventions spanning pre- and post-discharge periods (3 studies), and one multi-site study that included both inpatient and outpatient settings. Six studies were conducted in the US and 12 were conducted in Europe, with one study conducted in South Korea, and another in Mexico. The included studies measured adherence using objective measures such as e-monitoring/MEMS, pill counts, and blood plasma concentration levels; validated scales measuring adherence such as the Medication Adherence Questionnaire (MAQ), the Medication Adherence Rating Scale (MARS), and the Drug Attitude Inventory (DAI), which has been shown to correlate with other measures of adherence;[1] and a variety of other measures of adherence, some of which used multiple sources. The patient outcomes most frequently reported were positive and negative symptoms, symptom severity, functional impairment, and time to first readmission or hospitalization. Commonly used measures included the Positive and Negative Syndrome Scale (PANSS), the Clinical Global Impression scale (CGI), the Brief Psychiatric Rating Scale (BPRS), and the Global Assessment of Functioning (GAF). Tables 4-11 provide study detail, and a brief description of adherence and patient outcome measures are provided in Appendices E and F.

1a. What are the effects of medication adherence interventions on psychopharmacological adherence?

Multicomponent Behavioral Interventions

Summary: Findings of the included studies are mixed, and there is no consistent evidence from which to draw conclusions about the efficacy of multicomponent behavioral interventions on pharmacological adherence. Table 4 provides study detail.

Details: There are a wide range of behavioral interventions targeting medication adherence, including functional analysis (*eg*, identifying the antecedents to specific behaviors), positive reinforcement, relaxation techniques. CBT combines behavioral interventions with the identification and challenging of cognitive distortions (*eg*, overgeneralization, black and white thinking). Other interventions commonly combined into multicomponent interventions include psychoeducation and MI, a non-confrontational goal-oriented style focused on overcoming ambivalence related to behavior change. Compliance Therapy is a multicomponent intervention first studied by Hayward et al in 1995[63] and described fully in a manual by Kemp et al in 1997[64]

that combines MI, cognitive, and psychoeducation approaches targeting psychotic symptoms, focusing on illness and treatment history, beliefs and understanding of the illness, and ambivalence towards treatment and stigma. Adherence Therapy[65] is a manualized intervention that builds on Compliance Therapy, and is a patient-centered cognitive behavioral approach incorporating MI and emphasizing joint decision-making, medication problem solving, exploring ambivalence, and the discussion of beliefs and concerns about medication.

We identified 7 studies (2 high ROB,[43,45] 3 moderate ROB,[44,47,49] 2 low ROB[46,48]) examining multicomponent behavioral interventions, of which 2 examined Adherence Therapy. The first was an RCT examining clinically unstable outpatients and found that over a period of 12 months, there was no difference between Adherence Therapy and the health education controls.[46] The second study, also an RCT, included 5 sessions while participants were inpatients, and 3 sessions after release. At 12 weeks post-discharge, there was no difference in medication adherence between the Adherence Therapy group and controls.[48]

Four studies examined Compliance Therapy with mixed findings. A prospective cohort study conducted in a community setting found a significant improvement in adherence between baseline and the end of treatment (1 month) as assessed using the MARS; however, there was no significant improvement by 6 months follow-up, and no significant improvement as assessed using MEMS at either time point.[45] An RCT of inpatients compared Compliance Therapy to supportive counseling, and found significantly better adherence in the Compliance Therapy group at discharge, with differences between the 2 groups continuing through the 18-month follow-up period.[43] Two studies however, found no significant improvement in medication adherence associated with Compliance Therapy.[47,49]

Finally, one RCT of inpatients compared group CBT with MI to group psychoeducation with MI and found no difference between groups at 24 months follow-up.[44] Table 4 provides study detail.

Table 4. Psychotic Spectrum Disorders: Multicomponent Behavioral Interventions Medication Adherence Outcomes

Interventions Involving Family Members

Summary: Findings of the included studies show a generally positive effect associated with interventions for medication adherence involving family members.

Details: Interventions involving family members are often conducted in group settings, and often include psychoeducation, support for families, behavioral problem solving, and crisis management.[66]

Three RCTs (all moderate ROB) meeting inclusion criteria examined the effect of interventions involving family members.[50-52] Two studies included both an individual and a family component, with individual treatment conducted in a group setting.[51,52] Two studies involved interventions that included both the participant and family together,[50,52] with one study including a group intervention for relatives only.[51] Two studies found family interventions to be more effective than usual care,[51,52] and one study found no significant difference when controlling for time.[50] Table 5 provides study detail.

Abbreviations: NR = Not reported; NS = Not significant.

System-level Interventions

Summary: There is insufficient evidence regarding the efficacy of system-level interventions to improve medication adherence.

Details: System-level interventions include policies implemented at the system-level for all patients meeting predefined criteria, and may include screening, education, and other interventions.

One included RCT (moderate ROB) compared a system-level intervention to Compliance Therapy.[49] The system-level intervention included a brochure and questionnaire on antipsychotic treatment as a basis for conversation between participant/provider, a screening form for identification of compliance problems as the basis for participant/nurse conversation, a reminder box that contained medicine cards, dosage boxes, electronic alarm systems, medication reconciliation, and the requirement that providers adhere to clinical guidelines. Although the system-level group showed better adherence outcomes, differences were not significant. Table 6 provides study detail.

Pharmacist-led Interventions

Summary: Findings of the included studies are insufficient to determine the efficacy of pharmacist-led interventions.

Details: Pharmacist-led interventions are often brief interventions focused on education specific to medication, including the benefits, side effects, and potential consequences for discontinuing medication.

We identified one study (high ROB) examining a pharmacist-led intervention, which involved a group session that included a question and answer session about medication, rationale, risks of stopping, side effects, risk/benefit evaluations.[53] One session focused on antipsychotics, the second session focused on mood stabilizers. There was no significant difference between the pharmacist-led intervention and usual care. Table 6 provides study detail.

Technology Interventions

Summary: Findings of the included studies show a generally positive effect, with low strength of evidence.

Details: Technology interventions vary, and may include SMS or telephone reminders, e-monitoring using a variety of platforms, including MEMS caps, which record the time and date each time the cap is opened.[54]

We identified 4 studies (one high ROB,[55] 2 moderate ROB,[54,56] one low ROB[57]) examining technology interventions to improve psychopharmacologic adherence. Two RCTs compared e-monitoring to a variety of comparators.[55,57] One study found significantly better adherence when assessed using the e-monitor as compared with usual care, but not as assessed by pill counts.[57] The second study, which examined e-monitoring both as an intervention and a measure of adherence, compared adherence measured by e-monitoring, pill counts, and self-report using a validated scale, and found adherence in the e-monitoring group to be significantly higher than both pill counts by a pharmacist and self-report.[55] The third study compared a telephone and

SMS intervention to telephone only and SMS only. Results indicated that although adherence was better in the group receiving both phone and SMS, the differences were not significant, nor did adherence improve significantly for any of the groups over the duration of the study.[54] The fourth study compared daily SMS to usual care, and found significantly better adherence in the intervention group both at the end of the active phase (3 months) and at 6-months follow-up.[56] Table 6 provides more details about the included studies.

Other Interventions

Summary: Findings are insufficient to evaluate the efficacy of other interventions for psychopharmacologic adherence in patients along the psychotic spectrum.

Details: Four studies (one high ROB,[59] one moderate ROB,[60] 2 low ROB[57,58]) examined other interventions for medication adherence for people along the psychotic spectrum. Included studies examined MI, shared decision making, and Cognitive Adaptation Therapy (CAT). One study examined an MI intervention targeting positive and negative symptoms and cognitive deficits.[58] Results indicated no significant difference between the intervention and comparison group, with better adherence in patients prescribed depot antipsychotics regardless of group. A second study examined a shared decision intervention that included a shared decision aid booklet covering pros/cons of medication, psychoeducation, and a treatment agreement with their clinician.[59] No difference in adherence was found as compared to usual care. Two studies examined CAT, an intervention focused on individualized strategies and environmental supports – one comparing standard CAT to the medication adherence component of CAT alone (Pharm-CAT) and usual care,[60] and the other comparing Pharm-CAT to e-monitoring and usual care.[57] Results indicated no difference between CAT and Pharm-CAT, and that both CAT and Pharm-CAT resulted in better adherence than usual care through 15 months as evaluated by pill counts. The study also found CAT, but not Pharm-CAT, to be better than usual care over 15 months as evaluated by pharmacy refill rates.[60] There were no differences between Pharm-CAT and e-monitoring over 3 months as assessed using the e-monitor, and Pharm-CAT was associated with better adherence than e-monitoring alone or usual care as assessed by pill counts.[57] Table 7 provides more detail.

1b. What are the effects of medication adherence interventions on *long-acting injectable (depot) psychopharmacological* adherence?

Two studies (both moderate ROB) examined interventions targeting people along the psychotic spectrum using long-acting injectable (depot) antipsychotics, and both reported improved adherence.[61,62] The first study was an RCT of outpatients prescribed depot antipsychotics receiving an intervention that included psychoeducation, early warning sign detection, and family education. Results indicated better adherence for the intervention group versus usual care at both the end of the intervention phase (12 months) and at 24-months follow-up.[61] The second study was a prospective cohort study of homeless outpatients in a community setting receiving depot plus CAE, a manualized individual multicomponent behavioral intervention consisting of 4 modules (psychoeducation, substance use/modified Motivational Enhancement Therapy [MET], provider communication, medication management).[62] CAE is customized based on an assessment at baseline to identify each patient's adherence vulnerabilities and reasons for non-adherence, with one to 4 of the modules assigned based on the results of the assessment. Results indicated significantly improved adherence through 25 weeks. Table 8 provides more detail.

1c. What are the effects of medication adherence interventions on *non-psychopharmacological* adherence?

One RCT (moderate ROB) examined the effect of an intervention for medication adherence on non-psychopharmacological adherence in patients along the psychotic spectrum.[54] The intervention was a technology intervention comparing telephone and SMS to telephone or SMS alone. There was no significant difference between groups. Table 9 provides study detail.

Table 8. Outcomes Associated with Long-Acting Injectable Adherence

Beebe et al, 2014[54] G1: 10 G2: 10 G3: 10	Adults 21-68 with a diagnosis of schizophrenia or schizoaffective disorder receiving outpatient care. Community mental health	G1: TIPS + Text. TIPS is a manualized intervention providing weekly telephone support addressing taking medication, attending appointments, coping with symptoms, abstaining from alcohol and other drugs, and getting along with others. G2: TIPS only G3: Text only – text format of the TIPS protocol. Texts were delivered daily	G1: Weekly phone calls and daily texts for 3 months G2: Weekly phone calls for 3 months G3: Daily text messages for 3 months	Home pill counts or percentage of injections received vs prescribed for depot NR	1 Month: M(SD) G1 (N = 7): 82.1(19.9) G2 (N = 7): 73.1(21.8) G3 (N = 6): 82.2(26.5)	2 Months: M(SD) G1 (N = 8): 86.6(7.6) G2 (N = 6): 58.5(27.2) G3 (N = 5): 69.4(33.9)
						3 Months: M(SD) G1 (N = 8): 76.9(20.9) G2 (N = 6): 69.3(24.9) G3 (N = 5): 70.2(27.2)
				Mean non-psychiatric medication adherence scores for G1 were higher (by an average of 11.9%) than G3 at 2 of the 3 follow-ups, and higher than G2 (by an average of 14.9%) months 1, 2, 3. Post hoc analysis revealed that the power to examine non-psychiatric medication adherence was 25%.		

Note. Studies were conducted in the US unless otherwise specified. Brief descriptions of medication adherence assessments are reported in Appendix E.
Abbreviations: M = Mean; NR = Not reported; SD = Standard deviation; SMS = Short message service; TIPS = Telephone Intervention Problem Solving for Schizophrenia.

1d. What are the effects of these interventions on patient outcomes?

Twenty included studies examined a wide range of patient outcomes, including symptom severity, quality of life, functional impairment, insight, time to first readmission/hospitalization, time spent in the hospital, and time to relapse. Patient outcome scales are described in Appendix F.

Symptom Severity

Seventeen studies examined the effect of interventions for medication adherence on positive (*eg*, delusions, hallucinations, disorganized speech or behavior), negative (*eg*, reduced emotional responsiveness, speech, movement, socialization, motivation), or total symptom severity in patients along the psychotic spectrum.

Positive Symptoms

Four studies evaluated positive symptoms using PANSS or CGI. Interventions included MI,[58] a multicomponent behavioral intervention,[44] an intervention involving family,[52] and SMS reminders.[56] Only the family intervention resulted in a significant decrease in positive symptoms.[52] See Table 10 for more detail.

Negative Symptoms

Four studies evaluated negative symptoms using the PANSS scale or CGI, and findings associated with the interventions were mixed. Interventions included MI,[58] a multicomponent behavioral intervention,[44] an intervention involving family,[52] and SMS reminders.[56]

The group family intervention resulted in a significant decrease in negative symptoms as assessed by the PANSS at 12 months; however, there was no significant difference as assessed by the CGI negative symptom scale at 3 months. SMS reminder messages were associated with a greater degree of change at 3 months and a decrease in severity of negative symptoms at 6 months.[56] No other interventions were associated with a decrease in negative symptoms. Table 10 provides more detail.

Overall Symptom Severity

Seventeen studies evaluated total symptom severity using the PANSS, CGI, or BPRS, with mixed findings associated with the intervention. Of the 10 studies reporting PANSS scores,[44,45,47-49,52,55,58,61,62] four[48,52,55,62] reported significantly fewer symptoms associated with the intervention, including depot plus a customized multicomponent behavioral intervention at 25 weeks,[62] a group family intervention,[52] Adherence Therapy at 12-weeks post-discharge,[48] and e-monitoring and pill counts as compared with self-reported adherence. MI did not reduce symptom severity for the full sample; however, it was associated with greater general symptom score reductions in women.[58]

Nine studies assessed symptoms using the BPRS,[43,46,50,51,53,54,57,59,60,62] with 2 reporting better scores associated with the intervention. The first study, a study of homeless outpatients included depot plus a customized multicomponent behavioral intervention and reported improved scores at 13 and 25 weeks.[62] The second study compared family psychoeducation to usual care, with better BPRS scores for the intervention group at 12 and 24 months.[51] The other 6 studies did not find a difference in BPRS scores between groups.

Three studies reported CGI scores,[55,59,62] with e-monitoring[55] (at 8 weeks) and depot plus a customized multicomponent behavioral intervention for homeless participants[62] reporting better scores at 13 and 25 weeks. Table 10 reports study detail.

Quality of Life

Four studies[46,47,49,56] evaluated the effect of the interventions on quality of life, with no improvements associated with Adherence Therapy,[46] Compliance Therapy,[47,49] or a system-level intervention.[49] However, daily SMS reminders as compared with usual care resulted in better quality of life scores at the end of the intervention (3 months), but not at 6 months follow-up.[56] Table 10 reports study detail.

Functional Impairment

Eleven studies evaluated functional impairment using the GAF, Global Assessment Scale (GAS), or the Social and Occupational Functioning Scale (SOFAS).[43,47-49,51,52,57,59-62] The studies reported mixed findings, with some showing no effect and others a positive effect of medication adherence interventions on functional impairment. The 2 studies comparing interventions involving family members to usual care found the intervention group to be less impaired,[51,52] as did one study of depot plus CAE.[62] However, no improvement or group differences were found in studies examining Adherence Therapy,[48] e-monitoring,[57] a system-level intervention,[49] and shared decision-making.[59] Results of the 3 studies examining Compliance Therapy were mixed, with 2 studies reporting no effect of Compliance Therapy on functional impairment,[47,49] and one study reporting improvement in functional impairment associated with Compliance Therapy as compared to routine management and supportive counseling for up to 18 months.[43] Similar results were found for studies examining CAT and Pharm-CAT, with one study reporting no improvement over time and as compared to e-monitoring,[57] and a second study reporting higher functioning for CAT versus Pharm-CAT and usual care.[60] Higher functioning was associated with Pharm-CAT as compared to usual care at 3 and 6 months, with no difference thereafter. Table 10 reports study detail.

Time to First Readmission/Hospitalization

The 10 studies examining time to first readmission or hospitalization reported mixed findings associated with interventions to improve medication adherence. Three studies comparing interventions involving family members to usual care reported significantly fewer admissions or longer time to readmission/hospitalization associated with the family intervention.[50-52] One study comparing a system-level intervention to Compliance Therapy found that over one year, the system-level intervention resulted in longer time to readmission.[49] Two other studies examining Compliance Therapy[43,47] found that the intervention had no effect on readmission/ hospitalization, nor did MI,[58] depot plus CAE,[62] or shared decision making.[59] Table 10 provides more detail.

Time Spent in the Hospital

Three studies examined whether the interventions aimed at improving medication adherence had any effect on time spent in the hospital. Neither Compliance Therapy[43] nor a group multicomponent behavioral intervention[44] was associated with shorter stays; however, a family intervention was associated with fewer days in the hospital after rehospitalization at 24 months.[51] Table 10 provides study detail.

Time to Relapse

The 2 studies examining time to relapse reported better outcomes associated with the intervention, with longer time to relapse associated with a family intervention,[52] as well as both CAT and Pharm-CAT as compared to usual care.[60] Table 10 provides study detail.

Side Effects

One study compared a system-level intervention to Compliance Therapy and examined side effects (*eg*, psychic, neurological, autonomic) related to psychopharmacological interventions, and found fewer side effects associated with Compliance Therapy. Table 10 reports study detail.

Table 10. Psychotic Spectrum Disorders: Patient Outcomes

Study; N per Group	Sample and Setting	Intervention Groups	Intervention Intensity	Measure; Baseline	First Follow-up	Additional Follow-ups
Adherence Therapy						
Gray et al, 2006[46] G1: 204 G2: 205	Adults with clinically unstable schizophrenia requiring antipsychotic medication for ≥ 1 year post-baseline. 1e. What are the harms and costs related to these interventions?

Two studies evaluated costs related to interventions to improve medication adherence in patients along the psychotic spectrum.[42,57] The first study compared the costs related to the frequency and duration of service contacts for Compliance Therapy as compared with routine management and supportive counseling.[1] Results indicated no difference in costs between the 2 interventions, and a positive relationship between costs and adherence for both groups (*ie*, regardless of intervention, better adherence was related to more contact).[42] The second study[2] compared Pharm-CAT to e-monitoring and usual care, and found that the average costs of treatment per patients were higher (significance not reported) for participants in the Pharm-CAT group as compared to e-monitoring.[57] Table 11 reports study detail.

No studies reported harms specific to an intervention.

[1] Healey et al (1998)[42] found significantly better adherence associated with CT.

[2] Velligan et al (2008)[60] found no difference in adherence when comparing pharm-CAT to e-monitoring, with both groups significantly more adherent than usual care.

Study; N per Group	Sample and Setting	Intervention Groups	Intervention Intensity	Measure (range, direction)	Source	Baseline	First Follow-up	Additional Follow-ups
						Statistically significant positive correlations were found for the entire sample between (a) costs and changes in compliance, and (b) costs and changes in insight between one and 6 months. When the Compliance Therapy and control groups were analyzed separately, neither revealed an obvious efficiency advantage in terms of translating service inputs into subject outcomes. A positive association was found for G1 between change in compliance and costs over 1-6 months (*P* = .004) and change in insight and costs over the same period (*P* = .022). The only other significant correlation was between residual costs and change in compliance in the control group over the 7-12 month period (*P* = .023).

KEY QUESTION 2. ADULTS WITH BIPOLAR DISORDER

We identified 4 studies (all moderate ROB) meeting inclusion criteria for patients with Type I or Type II bipolar disorder.[41,67-69] All 4 studies examined interventions that included psychoeducation. One study examined the addition of individual psychoeducation to psychotherapy,[68] another examined group psychoeducation alone,[69] and the third examined the Life Goals Program,[67] which includes psychoeducation and individualized problem solving skills with a focus on self-management. The fourth study evaluated CAE, a customized behavioral multicomponent intervention in which participants were assigned to one to 4 modules (psychoeducation, substance use/modified MET, provider communication, medication management) based on an assessment at baseline.[41]

Two of the 4 studies were conducted in Iran (one in an outpatient hospital clinic and the other in private and university clinics), with the other 2 conducted in community mental health clinics in the US. Studies assessed adherence using the MARS, the DAI, pill counts, and other measures. Common patient outcomes reported were severity of depression, mania, and functional impairment, as assessed by the Hamilton Depression Rating Scale (HAM-D), the Young Mania Rating Scale (YMRS), and the GAF. Appendices E and F provide brief descriptions of adherence and patient outcome assessment tools.

2a. What are the effects of medication adherence interventions on *psychopharmacological* adherence?

Four studies examined interventions designed for psychopharmacological adherence. Two studies conducted in Iran examined psychoeducation alone, with one study focusing on individual sessions,[68] and the other focusing on a group intervention.[69] The first study randomized participants to standard psychotherapy plus individual psychoeducation (intervention group) or standard psychotherapy alone (control group), both of which included 8 weekly sessions followed by monthly question and answer sessions by phone for a total of 18 months.[68] The study evaluated the effect of the interventions on adherence using the MARS, and results indicated significantly better adherence in the intervention group at 6, 12, and 18 months (P = .008). Table 12 provides more detail.

In the second study participants were allocated to one of 3 groups – group psychoeducation, supportive group psychotherapy (placebo), or medication only (control).[69] The intervention group received weekly 90-minute sessions over a period of 9 weeks, with medication adherence assessed using the MARS at 3 and 6 months. Data from this study indicated better adherence in the intervention group as compared to both placebo and control ($F(2, 31) = 55.09$, $P = .0001$). Table 12 provides more detail.

The third study was an RCT evaluating the effect of the Life Goals Program,[70] a manualized structured group psychotherapy program focused on psychoeducation and individual application of problem solving skills.[67] Participants were randomized to either the Life Goals Program plus usual care (medication management, counseling, access to social services and case management), or usual care alone. The Life Goals Program consists of 2 phases. Phase I included 6 weekly group (6-8 members) sessions and targets issues related to medication adherence, with Phase II comprised of ongoing monthly group sessions focused on functional goal attainment. Participants were enrolled in Phase I, and encouraged to attend Phase II. Medication adherence was assessed at baseline and at 3, 6, and 12 months using the DAI, which assesses attitudes

towards psychotropic medication, and has been shown to correlate significantly with validated measures of medication adherence.[1] Participants were also asked to provide an estimate of their adherence to all psychopharmacological medications combined. Data from this study indicated no significant difference between groups. However, there was a large amount of missing data (only 75% of the intervention group and 81% of the control group participated in baseline plus one other assessment) and only 49% of the intervention group participated in most or all of the group sessions, with 37% never participating. The authors conducted a secondary analysis comparing those who had participated in 4 to 6 sessions, those participating in 1 to 2 sessions, and those never attending a group session. Results of the secondary analysis indicated a difference in the effect of the intervention between those participating in 4 to 6 sessions (effect size = .59), and those participating in 1-2 (effect size = .16), and no sessions (effect size = .07). Table 12 provides more detail.

The fourth study was a cohort study evaluating the effect of CAE delivered over 4 weekly, individual, 60-minute sessions and up to 2 follow-up telephone sessions over a 6-week period.[41] The DAI, the Morisky Scale, the Tablet Routine Questionnaire (TRQ) for both the previous week and the previous month, and pill counts were used to assess medication adherence outcomes at 6 weeks, 3 months, and 6 months. Findings indicated better DAI scores at both 6 weeks (P = .005) and at 6 months (P = .001), and better treatment adherence according to the Morisky Scale at 6 months (P = .001). Table 12 provides more detail.

2b. What are the effects of medication adherence interventions on *long-acting injectable (depot) psychopharmacological* adherence?

We identified no studies examining medication adherence interventions for long-acting injectable (depot) psychopharmacological adherence.

2c. What are the effects of medication adherence interventions on *non-psychopharmacological* adherence?

We identified no studies examining medication adherence interventions for non-psychopharmacological adherence.

				Only one-third of participants provided pill bottles, with only 2 participants at baseline and 3-months, and one participant at baseline and 6-months.		

Note. Studies were conducted in the US unless otherwise specified. Brief descriptions of medication adherence assessments are reported in Appendix E.
[1] Only 75% of the intervention group and 81% of the control group participated in baseline plus one other assessment, and only 49% of the intervention group participated in most or all of the group sessions, with 37% never participating.
Abbreviations: CAE = Customized adherence enhancement; DAI = Drug Attitude Inventory; ES = Effect size; MARS = Medication Adherence Rating Scale; M = Mean; MDN = Median; SD = Standard deviation; SE = Standard error; TRQ = Tablet Routine Questionnaire; WSRT = Wilcoxon signed-rank test.

2d. What are the effects of these interventions on patient outcomes?

The 4 studies meeting inclusion criteria for medication adherence outcomes in patients with bipolar disorder also reported data related to patient outcomes, including quality of life, depression, mania, functional impairment, global functioning/severity, positive and negative affective symptoms, and hospital readmissions. Appendix F provides a summary of the included patient outcome scales.

Quality of Life

One study, which evaluated the addition of 8 weekly individual psychoeducation sessions and short telephone contact for 18 months compared to standard psychotherapy, assessed quality of life using the World Health Organization Quality of Life instrument (WHOQOL-BREF) at baseline, 6, 12, and 18 months.[68] The WHOQOL-BREF includes the domains of physical health, mental health, social health, and the environment, and results indicated that mean scores (all time points combined) for the intervention group were significantly higher than the comparison group along all of the domains, indicating better quality of life (*P* = .000). Table 13 provides more detail.

Depression

Three studies assessed depression using the HAM-D.[41,67,68] Data from the first study, which assessed the addition of individual psychoeducation sessions in participants who had experienced at least 2 episodes of relapse in the past 2 years or had a history of 3 episodes in the past 5 years (intervention group baseline mean [M] = 4.24), found significantly lower scores in the intervention group at 6, 12, and 18 months (*P* = .000).[68] The second study, which evaluated the CAE in bipolar participants with poor adherence, found that while there was no significant difference from baseline to 3 months (M[SE] = 16.2[1.2], *P* = .246), as compared to baseline, HAM-D scores were significantly lower at 6 months (M[SE] = 15.3[1.6], *P* = .044).[41]

The third study compared the Life Goals Program, a group psychotherapy program including psychoeducation and individualized problem-solving, to treatment as usual (intervention group baseline M[SD] = 19.98[11.45]), and found no significant differences at 3, 6, and 12 months.[67] However, a mixed model repeated measures analysis found a trend (*P* = .056) indicating that higher baseline HAM-D scores predicted more negative attitudes towards medications over time regardless of intervention. In this study, only 49% of the intervention group participated in most or all of the group sessions, and 37% never attended a group session. See Table 13 for more detail.

Mania

Three included studies assessed mania.[41,67,68] Using the Bech Rafaelsen Mania Scale, one study[68] assessed the addition of individual psychoeducation versus standard psychotherapy versus standard psychotherapy alone and found significantly lower mean mania scores at 6, 12, and 18 months (*P* = .000). Similar to findings for depression, another study[41] found that while CAE resulted in no significant differences from baseline to 3 months (*P* = .101) on the YMRS, mania scores were significantly lower at 6 months (M[SE] = 9.6[1.0]) as compared with baseline (M[SE] = 14.2[1.2], *P* = .002). Also similar to findings for depression outcomes, a study[67] comparing the Life Goals Program group to participants receiving usual care found no difference in YMRS scores. Table 13 provides more detail.

Functional Impairment

Three included studies examined outcomes related to functional impairment, 2 of which used the GAF,[41,69] with one utilizing the predecessor to the GAF, the GAS.[67] One study compared group psychoeducation to a placebo group receiving supportive psychotherapy, and to a control group composed of participants experiencing euthymic mood.[69] GAF scores for all 3 groups were similar at baseline. Findings indicated that while there was no difference between the placebo and control groups, GAF scores for the intervention group were significantly higher than both placebo and control at 3 and 6 months (P = .0001), indicating higher levels of functioning.

Similar to other patient outcomes associated with CAE, there was no significant difference in functional impairment between baseline (M[SE] = 51.6[1.2]) and 3 months (M[SE] = 55.7[1.3], P = .072), but a significant improvement was observed from baseline to 6 months follow-up (M[SE] = 58.0[1.7], P = .001).[41] Similarly, there was no difference between the Life Goals Program group and usual care at 3, 6, and 12 months.[67] See Table 13 for more detail.

Global Functioning/Severity – Bipolar Disorder

One study examined the severity of depressive and manic episodes and the degree of change from the immediately preceding phase and from the worst phase of illness using the Clinical Global Impression scale for use in bipolar illness (CGI-BP), and found that CAE resulted no improvement between baseline (M[SE] = 4.4[.16]) and 3 months (M[SE] = 3.9[.21], P = .072), with significant improvement from baseline to 6-months follow-up (M[SE] = 3.6[.24], P = .001).[41] See Table 13 for more detail.

Positive and Negative Affective Symptoms

One study assessed positive and negative affective symptoms using the BPRS.[41] Unlike other patient outcomes associated with CAE, there was significant improvement from baseline (M[SE] = 43.6[1.8]) to both 3-months (M[SE] = 37.3[2.1], P = .003) and 6-months follow-up (M[SE] = 36.1[2.3], P = .001). Table 13 provides more detail.

Hospital Readmissions

One study examined hospital records to evaluate whether individual psychoeducation in addition to standard psychotherapy was associated with fewer hospital readmissions. Data indicated that over the 18-month study period, fewer participants in the intervention group were readmitted to the hospital as compared with participants receiving standard psychotherapy alone (.22% versus 1.41%, P = .000). See Table 13 for more detail.

2e. What are the harms and costs related to these interventions?

We identified no studies addressing the harms or costs of interventions for medication adherence in patients with bipolar disorder.

KEY QUESTION 3. ADULTS WITH PTSD

We identified no studies examining medication adherence interventions for patients with PTSD.

Table 13. Bipolar Disorder: Patient Outcomes

Note. Studies were conducted in the US unless otherwise specified. Brief descriptions of patient outcome assessments are reported in Appendix F.
[1] Only 75% of the intervention group and 81% of the control group participated in baseline plus one other assessment, and only 49% of the intervention group participated in most or all of the group sessions, with 37% never participating.
Abbreviations: BPRS = Brief Psychiatric Rating Scale; CAE = Customized adherence enhancement; CGI-BP = Clinical Global Impression – Bipolar scale; GAF = Global Assessment of Functioning; GAS = Global Assessment Scale; HAM-D = Hamilton Depression Rating Scale; MET = Motivational Enhancement Therapy; WSRT = Wilcoxon signed-rank test.

SUMMARY AND DISCUSSION

We reviewed 7,944 titles and abstracts from the search of electronic databases, bibliographies, and other sources, and 152 were identified as potentially relevant. Upon full-text review, we excluded 127 studies for a total of 24 included studies from 25 publications. Of the 518 clinical trials identified by our search of trial registry websites, one study met inclusion criteria;[40] however, this study and all data reported on ClinicalTrials.gov are represented in an included publication.[41] We identified 21 articles (20 primary studies) for Key Question 1, 4 primary studies for Key Question 2, and no primary studies for Key Question 3.

SUMMARY OF EVIDENCE BY KEY QUESTION

Key Question 1. In adults with psychotic spectrum disorders:

Overall there is insufficient evidence from which to draw conclusions about the effectiveness of interventions to improve medication adherence in patients with psychotic spectrum disorders.

Interventions vary widely, with included studies evaluating multicomponent behavioral interventions, interventions involving family members, interventions involving technology, pharmacist-led interventions, system-level interventions, and others. Overall, findings are mixed. However, there is low strength of evidence that interventions involving family members, and those involving technology, such as e-monitoring or daily reminder messages may result in improved psychopharmacological adherence; this indicates that additional evidence is needed before concluding either that the findings are stable or that the estimate of effect is close to the true effect. Table 14 provides additional detail.

There is limited evidence of the effectiveness of depot antipsychotics in combination with a medication adherence intervention, with studies reporting better adherence associated with a psychosocial intervention in patients prescribed a depot antipsychotic as compared with controls, and improved adherence in a homeless population associated with the prescription of depot and a customized multicomponent behavioral intervention. However, despite evidence suggesting a positive effect, the wide differences in the interventions, small sample sizes, the potential for sampling bias in populations prescribed depot antipsychotics, and lack of methodological rigor preclude drawing firm conclusions.

Only one study measured non-psychopharmacological adherence, and found no benefit associated with telephone and/or SMS support.

There is no clear evidence of the effect of medication adherence interventions on patient outcomes. Findings reported for positive, negative, and overall symptom severity are mixed, and there is little support that these interventions improve quality of life. Findings related to functional impairment are also mixed; however, there is limited evidence that interventions involving family members and those including the use of a depot antipsychotic may result in improved functioning. Similarly, while it is unclear whether medication adherence interventions in general are effective in reducing hospitalizations, the time to first hospital readmission, or time spent in the hospital, 2 studies reported a positive effect of interventions on time to relapse, and limited evidence suggests that in general, interventions involving family members may result in better patient outcomes.

Table 14. Psychotic Spectrum Disorders: Summary of Medication Adherence Outcomes

Type of Intervention	Study Design (Combined N)	Findings	Strength of Evidence	Comments
Behavioral Multicomponent - Adherence Therapy	2 RCTs (N = 370)	Mixed findings: one study (low ROB) reported better adherence compared to usual care on the MAQ and SAI-C at 12 months, and the other (low ROB) reporting no difference from usual care on the CDR, DAI-30, and MARS at 12 weeks post-discharge.	Insufficient	Evidence from only 2 studies, with mixed findings.
Behavioral Multicomponent - Compliance Therapy	2 RCTs (N = 130) 1 NRCT (N = 70) 1 Prospective Cohort (N = 30)	Mixed findings: better MARS scores with Compliance Therapy at 1 month but not 6 months in 1 study (high ROB); better DAI and compliance scores as compared with routine management plus supportive counseling through 18 month follow in 1 study (high ROB); no benefit to Compliance Therapy up to 6 months in 2 studies (compared to nonspecific counseling and Compliance Therapy; moderate ROB).	Insufficient	Inconsistent findings among 4 studies. Risk of bias due to study design.
Other Behavioral Multicomponent	1 RCT (N = 88)	No difference between group cognitive behavioral therapy (CBT) plus Motivational Interviewing (MI) and group psychoeducation plus MI (moderate ROB).	Insufficient	Evidence from only one study.
Depot plus Behavioral Multicomponent	1 Trial (randomization unclear) (N = 57) 1 Prospective Cohort (N = 30)	Findings indicated improved adherence related to the use of depot antipsychotics plus a behavioral multicomponent intervention (compared to usual care or no comparator) as measured by injection visits up to one year, and injection visits, TRQ, Morisky scale, DAI, and AMQ up to 25 weeks (moderate ROB).	Insufficient	Heterogeneity among interventions; risk of bias due to study design.
Family Intervention	3 RCTs (N = 449)	Better adherence with family interventions as measured by clinician rating/blood plasma and pharmacy records/family-report as compared to usual care in 2 studies (moderate ROB). No difference when controlling for time in a third study examining a culturally modified family intervention as compared to the standard family intervention and monthly sessions (moderate ROB).	Low	Heterogeneity among interventions.
System-level Intervention	1 NRCT (N = 70)	Nonsignificant trend towards better adherence for the system-level intervention, compared with Compliance Therapy (moderate ROB).	Insufficient	Evidence from only one study.
Pharmacist-led	1 Prospective Cohort w/post hoc comparison (N = 30)	No significant difference over time or between groups (high ROB).	Insufficient	Evidence from only one study; potential risk of bias due to study design flaws.
Technology Interventions	4 RCTs (N = 434)	Mixed findings on e-monitoring/MEMS: better adherence in 1 study as compared to pill counts and self-reported adherence (high ROB), conflicting results in 1 study as compared to a pharmacy based intervention and usual care (low ROB). Telephone plus SMS resulted in nonsignificant adherence improvement vs telephone or SMS alone (moderate ROB); SMS alone resulted in significantly better adherence than usual care (moderate ROB).	Low	Mixed findings and heterogeneous interventions.

Type of Intervention	Study Design (Combined N)	Findings	Strength of Evidence	Comments
Motivational Interviewing (MI)	1 RCT (N = 114)	One study found no benefit to MI over usual care as measured by the MAQ or DAI (low ROB).	Insufficient	Evidence from only one study.
Cognitive Adaptation Training (CAT)	2 RCTs (N = 240)	One study found that both CAT and Pharm-CAT resulted in better adherence than usual care, with no difference between the 2 (moderate ROB). The second study comparing Pharm-CAT to e-monitoring reported mixed results (low ROB).	Insufficient	Evidence from 2 studies that used different comparators.
Shared Decision Making	1 RCT (N = 107)	One study found no benefit to a shared decision-making over usual care as measured by the MARS and plasma levels (high ROB).	Insufficient	Evidence from only one single study.

Note. Studies comparing interventions may be accounted for more than once.
Abbreviations: AMQ = Attitude towards Medication Questionnaire; CAT = Cognitive Adaptation Training; CBT = Cognitive Behavioral Therapy; CDR = Concentration to Dose Ratio; DAI = Drug Attitude Inventory; MAQ = Medication Adherence Questionnaire; MARS = Medication Adherence Rating Scale; MEMS = Medication Event Monitoring System; MI = Motivational Interviewing; NRCT = Non-randomized controlled trial; ROB = Risk of bias; SAI-C = Schedule for the Assessment of Insight - C; TRQ = Tablet Routine Questionnaire.

Key Question 2. In adults with bipolar disorder:

The 4 studies meeting inclusion criteria for Key Question 2 provide limited evidence of the effectiveness of interventions for medication adherence in patients with bipolar disorder. Three of the 4 studies found a positive effect on psychopharmacological adherence associated with an adherence intervention, with high rates of attrition in the one study reporting no effect. Despite evidence suggesting a generally positive effect, the strength of the evidence is insufficient and thus precludes drawing conclusions, due to the fact that the interventions were heterogeneous, sample sizes were small, and 2 studies showing a positive effect were conducted in Iran, calling into question applicability (see Table 15).

There is no clear evidence to support conclusions regarding the effect of interventions for improving medication adherence on patient outcomes. Findings related to depression, mania, and functional impairment were mixed, and despite limited evidence supporting improvement, the lack of high quality studies, heterogeneity of the interventions, and setting preclude the ability to draw conclusions.

Key Question 3. In adults with PTSD:

We identified no studies meeting inclusion criteria for Key Question 3.

LIMITATIONS

Our review has a number of limitations. Despite restricting included studies to randomized and non-randomized controlled trials and observational studies that controlled for important confounding variables *and* included either a comparison group or examined a trend controlling for time (see Table 3), we rated only 4 of the 25 included studies (all 4 were trials) as high-quality studies with a low risk of bias,[46,48,57,58] with 4[42,43,55,59] of the 19 trials and 2[45,53] of the 6 observational studies determined to have a high risk of bias. In many studies, sample sizes were small, bringing into question statistical power. While it would have been ideal to overcome the issue of power by combining studies quantitatively, heterogeneity between studies precluded us from doing so. Studies included in this review evaluate a wide range of interventions in a variety of settings, with vast differences in intervention characteristics and implementation; specific interventions were rarely examined in more than one study. Furthermore, a wide range of measures were used to assess medication adherence, ranging from objective measures to validated short self-report scales, which often found different results even within the same study. Finally, although we did conduct a search for grey literature, we were unable to conduct a formal assessment of publication bias.

Table 15. Bipolar Disorder: Summary of Medication Adherence Outcomes

Type of Intervention	Study Design; (Combined N)	Findings	Strength of Evidence	Comments
Psychoeducation (individual/group)	1 RCT (N = 108) 1 NRCT (N = 45)	Both individual and group psychoeducation resulted in better medication adherence pharmacotherapy alone or pharmacotherapy with standard psychotherapy (moderate ROB).	Insufficient	Evidence from only 2 studies, external validity due to setting.
Psychoeducation plus problem solving	1 RCT (N = 164)	There was no improvement in medication adherence associated with the intervention as compared to usual care (moderate ROB).	Insufficient	Evidence from only one study. Only 75% of the intervention group and 81% of the control group participated in baseline plus one other assessment, and only 49% of the intervention group participated in most or all of the group sessions, with 37% never participating.
Customized Behavioral Multicomponent (psychoeducation, substance use/modified MET, provider communication, medication management)	1 Prospective Cohort (N = 43)	Customized adherence enhancement (CAE) was associated with better adherence and attitudes towards medication at 3 and 6 months (moderate ROB).	Insufficient	Evidence from only one study; risk of bias due to study design.

Abbreviations: CAE = Customized adherence enhancement; MET = Motivational Enhancement Therapy; NRCT = Non-randomized controlled trial; RCT = Randomized controlled trial; ROB = Risk of bias.

DISCUSSION

We found 24 studies in 25 publications with the potential to inform policies and practices related to medication adherence in patients with severe mental illness in the VHA. Twenty studies (reported in 21 articles) examined patients with psychotic spectrum disorders, and 4 studies were in patients with bipolar disorder. We identified no studies examining patients with PTSD. The interventions designed to improve medication adherence across Key Questions 1 and 2 differed widely, with very few studies evaluating the same specific interventions. Despite a variety of interventions designed to increase psychopharmacological adherence, study limitations (*eg*, differences in population and setting, heterogeneity among studies, a wide range of comparators, and the challenge of evaluating complex interventions), as well as concerns regarding applicability to the VHA, preclude us from drawing strong conclusions.

There is limited evidence that the involvement of family members, the use of technology (*eg*, e-monitoring, SMS, telephone), and that the combination of a depot antipsychotic and another intervention may be effective in improving adherence. However, these findings must be interpreted with caution, given the heterogeneity among interventions, the difficulty in determining the contribution of the depot antipsychotic versus the adherence intervention, the methodological limitations, and the lack of consistent replication of any specific intervention. With the exception of interventions involving technology and system-level interventions, many interventions include behavioral or other techniques (*eg*, MI) that are flexible and designed to adapt to different settings and patients. While these techniques have been found effective in the treatment of other mental health conditions (*eg*, anxiety, depression, substance abuse), additional research of standardized interventions designed to improve medication adherence is needed to replicate findings across settings and populations in order to better understand their effect on adherence and patient outcomes. Similarly, many of the included studies compare interventions for medication adherence to usual care, rather than an active comparator. Given the population and the nature of mental illness, it is possible that the lack of active controls may result in more frequent provider interaction for the intervention group than for those receiving usual care. More frequent contact alone has the potential to result in improved outcomes, and it is impossible to ascertain whether any effect was due to the intervention or to increased attention. Finally, sampling bias may exist related to baseline differences in the adherence of individuals selected to enroll in studies examining interventions designed to improve medication adherence and those who do not – particularly in studies examining long acting injectable depot antipsychotics.

An additional challenge in accurately assessing the body of research examining medication adherence is the wide range of methods used to assess adherence. We limited our inclusion to studies that assessed adherence using an objective measure such as blood plasma concentration levels, pill counts, e-monitoring/MEMS caps, or using a validated adherence scale.[1] For studies using multiple adherence measures, it was not uncommon for the determination of adherence to be incongruent, leading to questions related to the validity of commonly used and validated objective and subjective measures.

There is a paucity of research examining the effect of medication adherence interventions on non-psychopharmacological interventions. Given the risk of comorbid health conditions (*eg*, diabetes, hypertension) in persons with serious mental illness, future research should evaluate the impact of adherence interventions aimed at prevalent comorbid non-psychiatric conditions.

Furthermore, we identified no studies evaluating the potential harms that may result from these interventions. Despite the fact that the potential for harm appears to be low as compared to the risks associated with both the use of and non-adherence to prescribed medication, research documenting relative risk is warranted. Similarly, very few studies evaluated differential effects in subpopulations. It is important to understand whether both the benefits and potential harms differ by subgroup or clinical subpopulation and whether one type of intervention may be more effective than others for a given population or setting.

We identified no studies examining interventions to improve medication adherence in patients with PTSD. Although trauma processing therapies are often the first line of treatment for patients with PTSD, pharmacological interventions are commonly used as adjunctive therapy to alleviate associated symptoms and to treat comorbid conditions. There is limited evidence to suggest that adherence to medication is poor in Veterans with PTSD who are taking medication. Therefore, future research is warranted to determine whether improvements in adherence in this population can be achieved through the use of interventions, or by adapting interventions developed for other patient populations.

Recommendations for Future Research

Interventions to improve medication adherence in patients with psychotic spectrum disorders and bipolar disorder warrant further investigation, particularly in the form of well-designed RCTs with active comparators of adequate sample size and duration. Furthermore, few studies examine the same intervention, and replication is needed in order to draw conclusions about the effectiveness of a specific program. Several small studies suggest the effectiveness of some of the interventions (*eg*, interventions including family members). However, many of the interventions are multicomponent and complex, differ widely in their components and implementation, and thus research evaluating standardized interventions is needed.

Research evaluating the effectiveness of interventions to improve medication adherence in patients with PTSD is lacking and needed. For all populations examined in this report, future research is needed to evaluate the effect of these interventions on non-psychopharmacological interventions. In addition, future studies should examine potential adverse events associated with medication adherence interventions. Objective measures should be used to measure medication adherence, and the identification and validation of a gold-standard assessment tool for medication adherence is warranted. Finally, more research is necessary to determine the cost effectiveness and feasibility of interventions for medication adherence in the VHA.

CONCLUSION

Findings from the studies examining interventions to improve medication adherence in patients with psychotic spectrum disorders are mixed and evaluate a wide range of heterogeneous interventions. Sample sizes were generally small, studies often lacked an active comparison group, and there was wide variation in how adherence was measured among studies. There is limited evidence to support improved adherence associated with interventions involving family members, those involving technology, and those combining a depot antipsychotics with another intervention. Findings were mixed regarding the effectiveness of multicomponent behavioral interventions, with no support for Adherence or Compliance Therapies. In addition, no clear evidence exists to support conclusions regarding the effect of medication adherence interventions on patient outcomes. Very few studies examined interventions for medication adherence in

patients with bipolar disorder, and while in general there appears to be a positive effect of these interventions on adherence in this population, interventions were heterogeneous and more research is needed. No studies were found examining PTSD populations. For all populations, methodologically rigorous replication studies of standardized treatments using objective or validated subjective measures of adherence are needed to confirm preliminary results, as is research examining the costs and potential harms associated with the wide array of interventions designed to improve medication adherence.

APPENDIX A. TECHNICAL EXPERT PANEL

Jennifer Bean, Pharm.D (VA)
Clinical Pharmacy Specialist (Psychiatry and Pharmacotherapy), VA Tennessee Valley Healthcare System

Joyce Cramer (former VA)
Medical Research Consultant
Associate Research Scientist in Psychiatry, Yale University Department of Psychiatry, retired
West Haven VA Medical Center, retired

Colin Depp, PhD (VA)
Associate Professor of Psychiatry, University of California, San Diego
Staff Psychologist, VA San Diego Health Care System

Walid Gellad, MD, MPH (VA)
Core Investigator, Center for Health Equity Research and Promotion
Staff Physician, VA Pittsburgh Healthcare System
Assistant Professor of Medicine, University of Pittsburgh School of Medicine
Assistant Professor of Health Policy and Management, University of Pittsburgh Graduate School of Public Health

Jennifer Houser, Pharm.D (VA)
Clinical Pharmacy Specialist (Mental Health), William Jennings Bryan Dorn VA Medical Center

Teresa Hudson, Pharm.D, PhD (VA)
Associate Director, Division of Health Services Research, Psychiatric Research Institute, University of Arkansas for Medical Sciences School of Medicine
Associate Director, VA Health Services Research & Development Center for Mental Healthcare and Outcomes Research, Central Arkansas Veterans Healthcare System

Judith Hyatt, Pharm.D (VA)
Clinical Pharmacist (Psychiatry and Pharmacotherapy) VA Western New York Healthcare System

Martha Sajatovic, MD
Professor of Psychiatry and of Neurology, University Hospitals Case Medical Center
Willard Brown Chair in Neurological Outcomes Research
Director, Neurological and Behavioral Outcomes Center

Todd Semla, Pharm.D, MS (VA)
National Pharmacy Benefits Management (PBM) Clinical Pharmacy Program Manager - Mental Health & Geriatrics
Clinical Pharmacy Specialist (Psychiatry and Geriatrics)

Marcia Valenstein, MD, MS (VA)
Staff Psychiatrist, VA Ann Arbor Healthcare System
Senior Research Scientist, VA Health Services Research and Development Service and the Serious Mental Illness Treatment Research and Evaluation Center (SMITREC), VA Ann Arbor Healthcare System
Professor of Psychiatry, University of Michigan

Dawn Velligan, PhD
Director, Division of Community Recovery, Research and Training
Professor of Psychiatry, Henry B. Dielmann Chair, University of Texas Health Science Center, San Antonio

Corrine Voils, PhD (VA)
Research Health Science Specialist, Durham Center for Health Services Research in Primary Care, VA Health Sciences Research and Development Service
Social Psychologist, Durham VA Medical Center
Professor of Medicine, Division of General Internal Medicine, Duke University Medical Center
Daina Wells, Pharm.D. (VA)

Program Manager, Academic Detailing Program at the Department of Veterans Affairs
VACO Pharmacy Benefits Management
Clinical Pharmacist (Psychiatry and Pharmacotherapy)

John Zeber, PhD, MHA (VA)
Co-director, Health Outcomes Core, Center for Applied Health Research, Internal Medicine
Investigator, Central Texas Veterans Healthcare System
Associate Professor, Texas A&M Health Science Center College of Medicine
Member, International Society for Pharmacoepidemiology Outcomes Research (ISPOR) and ISPOR National Working Group on Medication Compliance

APPENDIX C. STUDY SELECTION: INCLUSION/EXCLUSION CRITERIA FOR TITLE/ABSTRACT REVIEW

Instructions:

- In Abstrackr, a √ designates a study as included, a **?** as unknown, and an **X** will exclude the study. See table below for inclusion/exclusion criteria.
- When you are looking at an abstract, you will see a box to the left that is titled tags & notes. Please click "tag study" and tag the following:
  - If you are excluding a study or are unsure, but think it is appropriate background information, please tag the study as **B**
  - If the study meets all inclusion criteria except for study design, and the study is a cross-sectional study, please exclude the study but add the tag **CS.**
  - If the study meets all inclusion criteria except for study design, and the study is a systematic review, please exclude the study but add the tag **SR.**
- On the bottom of the screen, you will see a series of thumbs ups and thumbs downs next to a box with the word "term" next to it. Adding a term highlights it in both the abstract you are viewing, as well as all subsequent abstracts viewed by yourself and others. This allows for faster screening. A thumbs up indicates that it is a relevant term (two thumbs up = highly relevant), and a thumbs down indicates that the term is not relevant. Using these terms is optional; however, if you do see terms in abstracts that would suggest that the study is relevant or not (*eg*, specific med adherence outcomes, "adult," schizophrenia, bipolar, PTSD, common clinical outcomes, *etc*) that might make the screening process faster for everyone, feel free to use them!
- Please note – if you are unsure about whether the study meets criteria (*eg*, population specifies mental health disorders, but not which ones, or doesn't state what they used to measure med adherence, please code **?**, and we'll look at the full text).

While likely unnecessary, if you feel you need more guidance on the use of Abstrackr, see an instructional video: https://www.youtube.com/watch?v = 34Yb-ac9ULM

Include (Code √) if the study is/does (all criteria below must be met):	Exclude (Code X) if the study is/does/has (any of the below):
Language: English	**Language:** Non-English Language
Population: Human Participants	**Population:** Non-human "participants"
Age: Adults 18+	**Age:** < 18 years of age
Condition: Includes individuals diagnosed with Psychotic Spectrum Disorder –OR- Bipolar Disorder –OR- PTSD	**Condition:** No diagnosis of Psychotic Spectrum Disorder –OR- Bipolar Disorder –OR- PTSD
Intervention: Includes interventions designed specifically or are being specifically used to increase medication adherence	**Intervention:** No med adherence intervention, or the interventions are not specifically designed or used in a way to specifically addresses medication adherence (*eg*, broader more general group therapy or other types of therapies)
Comparator: Includes a comparison group (*eg*, another intervention, no intervention, usual care).	**Comparator:** No comparison group
Med Adherence Outcome(s): Must be the primary outcome –AND- must be an objective outcome (*eg*, medication container with electronic monitoring, pill counts, biological marker, observed intake, medication possession ratio [MPR], medication plasma level, electronic ingestible event marker) –OR- a validated subjective outcome (*eg*, self-report measure or scale such as the Morisky-9 [MMAS-8], Morisky-4 [MMAS-4 or MAQ])	**Med Adherence Outcome(s):** Not the primary outcome –OR- Patient self-report, caregiver report, case manager report, clinician's view based on therapeutic response, and other non-validated subjective outcomes.
Patient Outcome: Includes a patient outcome that is related to the medication adherence intervention AND medication adherence outcome reported.	**Patient Outcome:** No patient outcome that is related to the medication adherence intervention AND medication adherence outcome reported.

Study Design: Trials, case-controlled, and cohort studies	**Study Design:** Reviews (systematic or non-systematic), case series, case study, case report, qualitative, commentary, letter to the editor, and any other study design not meeting inclusion criteria.

Note. If at any time you are unsure of whether the study should be included, code **?**

APPENDIX D. STUDY SELECTION: INCLUSION/EXCLUSION CRITERIA FOR FULL-TEXT REVIEW

1. Language: Is the full text of the article in English?
   Yes…….....….....…….....……..…….....Proceed to #2
   No .....……...…..…..…..…..……Code **X**. STOP
2. Population: Is the population human participants?
   Yes ……..……..……Proceed to #3
   No ……..…. Code **X.** Add code **B** if retaining for background/discussion. STOP
3. Population: Are the participants adults (18 or over) in general mental health settings (inpatient or outpatient – forensic patients/prisoners are excluded)?
   Yes ……..……Proceed to #4
   No …… Code **X.** Add code **B** if retaining for background/discussion. STOP
4. Medication Adherence Intervention: Does the article include information relevant to interventions specifically designed to increase medication adherence?
   Yes ……..……..……Proceed to #5
   No …… Code **X.** Add code **B** if retaining for background/discussion. STOP
5. Disease Condition: Does the intervention focus on patients with psychotic spectrum disorders, bipolar disorder, or posttraumatic stress disorder (PTSD)?
   Yes ……..……Proceed to #6
   No …… Code **X.** Add code **B** if retaining for background/discussion. STOP
6. Comparator: Is there a comparison group (*eg*, another intervention, no intervention, usual care), or are there more than two time points if no comparison group exists?
   Yes ……..……Proceed to #7
   No …… Code **X.** Add code **B** if retaining for background/discussion. STOP
7. Medication Adherence Outcomes: Are the outcomes objective (*eg*, medication container with electronic monitoring [*eg*, MEMS], pill counts, biological markers, observed intake, medication possession ratio, medication plasma level, electronic ingestible event marker) or measured subjectively by a validated patient self-report scale or measure (*eg*, not patient self-report or report by caregiver, case manager, not clinician's view on adherence based on therapeutic response).
   Yes…….Proceed to #9
   No ……Code **X.** Add code **B** if retaining for background/discussion. STOP
8. Clinical Outcome: Is a clinical outcome related to the medication adherence intervention and the medication adherence outcome reported?
   Yes……Proceed to #10
   No……Code **X.** Add code **B** if retaining for background/discussion. STOP
9. Study Design: Is the study design a cross-sectional study or a simple pre-post, or qualitative study, or a non-systematic literature review, case study, case series, case report, commentary, or letter to the editor??
   Yes……Code **X**. Add code **B** if retaining for background/discussion. STOP
   No……Code R. Stop
   Unknown ……Code U. Stop

APPENDIX E. MEDICATION ADHERENCE OUTCOME MEASURES

Abbreviation	Name	Description	Source
AMQ	Attitude towards Medication Questionnaire	Semi-structured interview. Higher scores indicate a better attitude towards medication.	Clinician rated
CDR	Concentration to Dose Ratio	Serum concentration for primary antipsychotic with higher CDRs indicating better adherence.	Blood serum
CSRI	Client Service Receipt Inventory	Measures the frequency and duration of service contacts.	Self-report information, supplemented by case notes and hospital records
	Kemp scale[43]	Compliance scale rated on a seven-point rating scale with higher scores indicating greater compliance	Multiple sources, including nurse assessed
DAI	Drug Attitude Inventory	Shown to be associated with degree of adherence to psychotropic medication, and is a true/false questionnaire that assesses patients' attitudes, experience, locus of control, attitudes towards medication. Scores range from 0-10 with higher scores indicating better attitudes towards medication.	Self-report
MAQ	Medication Adherence Questionnaire	4-item measure that includes yes/no questions about forgetting to take medicine, carelessness with medicine, and discontinuation. A higher score indicates poorer treatment adherence.	Self-report
MARS	Medication Adherence Rating Scale	10-item yes or no assessment of medication adherence, and was translated to Farsi and validated. (0-9 [one neutral question], higher scores indicate better adherence).	Self-report
MEMS	Medication Event Monitoring System	Medication vial cap that electronically records the date/time of bottle opening.	Electronic monitoring
	Morisky Scale	Assesses medication adherence, feelings about medication, with higher scores indicating poorer adherence	Self-report
SAI-C	Schedule for the Assessment of Insight - C	Therapist rating of adherence ranging from 1 (complete refusal) to 7 (active participation in treatment) based on a semi-structured interview.	Clinician rated
TRQ	Tablet Routine Questionnaire	Shows a high correlation with lithium levels and identifies partial and full adherence in the previous 7 and 30 days.	Self-report

APPENDIX F. PATIENT OUTCOME MEASURES

Abbreviation	Name	Description	Source
	Bech Rafaelsen Mania Scale	Assesses 11 items (elevated mood, pressure of speech, increased social contact, increased motor activity, sleep disturbances, social activities and distractibility, hostility and irritability, increased sexual activity, increased self-esteem, flight of thoughts, and noise level of speech and other vocal activity).	Self-report Administered by Psychologist
BPRS	Brief Psychiatric Rating Scale	Consists of items measuring positive symptoms, negative symptoms, depression and anxiety and manic excitement or disorganization with higher scores indicating greater severity.	Clinician assessed
BPRS–E	Brief Psychiatric Rating Scale – Expanded	Consists of 24 items measuring positive symptoms, negative symptoms, depression and anxiety and manic excitement or disorganization with higher scores indicating greater severity.	Clinician assessed
CGI	Clinical Global Impression scale	Rating scale designed to assess severity and the degree of change from the immediately preceding phase and from the worst phase of illness. Higher scores indicate greater severity.	Clinician assessed
CGI –SGH	Clinical Global Impression – Schizophrenia scale	Rating scale designed to assess severity and the degree of change from the immediately preceding phase and from the worst phase of illness. Higher scores indicate greater severity.	Clinician assessed
EQ-5D	EuroQoL	Assesses quality of life differences in patients with schizophrenia of differing degrees of severity. Higher values indicate higher quality of life ratings.	Self-report
GAF	Global Assessment of Functioning	Assesses function impairment caused by illness, with scores ranging from 0-100 and higher scores indicating higher levels of functioning.	Clinician rated
GAS	Global Assessment Scale	Assesses function impairment caused by illness, with scores ranging from 0-100 and higher scores indicating higher levels of functioning.	Clinician assessed
HAM-D	Hamilton Depression Rating Scale	24 item scale assessing depression with scores ranging from 0-74, with higher scores indicating more severe depression.	Self-report
LEE	Level of Expressed Emotion	30 item measure assessing critical comments, emotional over-involvement, and hostility.	Family rated
PANSS	Positive and Negative Syndrome Scale	Used to rate positive symptoms (range 7-49), negative symptoms (range 7-49), and general symptoms (range 15-112) of schizophrenia on a 7 point scale. Higher scores indicate higher severity.	Clinician assessed
QLF	Quality of Life Scale	21-item scale based on semi-structured interview addressing intrapsychic foundations, interpersonal relations, instrumental role, and common objects and activities.	Clinician assessed
SAI	Schedule for Assessment of Insight	Scores expressed as a percentage of maximum insight. Higher values indicate greater insight	NR
SAI-E	Schedule for Assessment of Insight- Expanded	Scores expressed as a percentage of maximum insight. Higher values indicate greater insight	NR

Abbreviation	Name	Description	Source
SF-36	Short Form Health Survey	Self-report multidimensional survey measure of health-related quality of life (QOL) and well-being. The mental component summary score (MCS) was used as the main QOL outcome measure, as it has been shown to have good sensitivity to change, which is uncommon among QOL measures.	Self-report
SOFAS	Social and Occupational Functioning Scale	Assesses social, work and school functioning. Higher sores increase higher adaptive functioning	Self-report
SWN	Subjective Well-being on Neuroleptic Treatment Scale	20-item scale measuring mental functioning, social integration, emotional regulation, physical functioning, and self-control.	Self-report
UKU	UKU Side Effects Rating Scale	Semi-structured interview to assess the side effects of psychopharmacological interventions in the past 3 days.	Clinician assessed
WHOQOL-BREF	World Health Organization Quality of Life instrument – Abbreviated version	Quality of life questionnaire consisting of 26 items assessing physical, psychological, and social health and the environment. Scores for each domain are transformed to a 0-100 scale, with higher indicating better quality of life.	Self-report Administered by Psychologist
YMRS	Young Mania Rating Scale	Assesses mania, with scores ranging from 0-44 with higher scores indicating more severe mania.	Self-report

APPENDIX G. RISK OF BIAS: TRIALS

RISK OF BIAS: TRIALS, PART 1

Author, Year	Method of randomization adequate?	Allocation of treatment adequately concealed?	Were providers blinded to intervention or exposure status of participants?	Participants blinded to intervention or exposure status?	Outcome assessors blinded to intervention or exposure status of participants?
Bahredar et al, 2014[69]	NR	NR	NR	NR	NR
Barkhof et al, 2013[58]	Yes	Yes	No	Yes	Yes
Bechdolf et al, 2005[44]	Yes	Yes	Yes	Unclear	Yes
Beebe et al, 2014[54]	Yes	Unclear	No	No	Yes

Velligan et al, 2013[57]	Yes	NR	Yes	NR	Yes	Yes	Low

APPENDIX H. RISK OF BIAS: OBSERVATIONAL STUDIES

RISK OF BIAS: OBSERVATIONAL STUDIES, PART 1

Author, Year	Were providers blinded to intervention or exposure status of participants?	Participants blinded to intervention or exposure status?	Outcome assessors blinded to intervention or exposure status of participants?	Did strategy for recruiting participants into study differ across study groups?	Baseline characteristics similar between groups? If not, did analysis control for differences?
Byerly et al, 2005[45]	Unclear	Unclear	Yes	No	Yes
Kavanagh et al, 2003[53]	Unclear	Yes	Unclear	No	Unclear
Lee et al, 2010[61]	Unclear	No	Yes	No	Yes
Sajatovic et al, 2012[41]	NA	NA	NR	No	NA
Sajatovic et al, 2013[62]	NA	NA	NA	No	NA
Skarsholm et al, 2014[49]	No	No	No	No	Yes

RISK OF BIAS: OBSERVATIONAL STUDIES, PART 2

Author, Year	Impact from any concurrent intervention or unintended exposure that might bias results ruled out?	Did variation from study protocol compromise study conclusions?	High rate of differential or overall attrition?	Did attrition result in difference in group characteristics between baseline (or randomization) and follow-up?	Analysis conducted on an intention-to-treat (ITT) basis?
Byerly et al, 2005[45]	Unclear	Unclear	NA	NA	Unclear
Kavanagh et al, 2003[53]	NR	Unclear	No	NA	Unclear
Lee et al, 2010[61]	Yes	NR	Yes	No	Yes
Sajatovic et al, 2012[41]	No	NR	Yes	NA	NR
Sajatovic et al, 2013[62]	Unclear	Unclear	Yes	No	Unclear
Skarsholm et al, 2014[49]	Unclear	No	No	No	Yes

RISK OF BIAS: OBSERVATIONAL STUDIES, PART 3

Author, Year	Inclusion/exclusion criteria measured using valid and reliable measures, implemented consistently across all study participants?	Medication adherence outcomes assessed using valid and reliable measures, implemented consistently across all study participants? When adherence requires skills (*eg*, pill bottle, SMS), does the intervention measure or account for varied skill levels?	Do authors justify medication adherence thresholds?	Are health outcomes assessed using valid and reliable measures, implemented consistently across all study participants?	Harms assessed using valid and reliable measures, implemented consistently across all study participants?
Byerly et al, 2005[45]	Yes	Yes	Yes	Yes	NR
Kavanagh et al, 2003[53]	Yes	Yes	Yes	Yes	NR
Lee et al, 2010[61]	Yes	Yes	Yes	Yes	NR
Sajatovic et al, 2012[41]	Yes	Yes	No	Yes	NR
Sajatovic et al, 2013[62]	Yes	Yes	Unclear	Yes	Yes
Skarsholm et al, 2014[49]	Yes	Yes	Yes	Yes	Yes

RISK OF BIAS: OBSERVATIONAL STUDIES, PART 4

Author, Year	Potential outcomes pre-specified by researchers? Are all pre-specified outcomes reported?	Were incomplete outcome data adequately addressed?	Important confounding and modifying variables taken into account in the design and/or analysis? (*eg*, through matching, stratification, multivariable analysis, or other approaches?)	Additional Bias: Was the study apparently free of other problems that could put it at a high risk of bias? If no, please describe	Risk of Bias
Byerly et al, 2005[45]	Yes	Unclear	Yes	Yes	High
Kavanagh et al, 2003[53]	Yes	NR	Unclear	Unclear	High
Lee et al, 2010[61]	Yes	NR	No	Yes	Moderate
Sajatovic et al, 2012[41]	Yes	No	Unclear	Yes	Moderate
Sajatovic et al, 2013[62]	Yes	Unclear	Yes	Yes	Moderate
Skarsholm et al, 2014[49]	Yes	Yes	Yes	Yes	Moderate

APPENDIX I. PEER REVIEW COMMENTS/AUTHOR RESPONSES

Question Text	Reviewer Number	Comment	Response
Are the objectives, scope, and methods for this review clearly described?	1	Yes	Noted.
	3	Yes	Noted.
	4	Yes	Noted.
	5	Yes	Noted.
	6	Yes	Noted.
Is there any indication of bias in our synthesis of the evidence?	1	No	Noted.
	3	No	Noted.
	4	No	Noted.
	5	No	Noted.
	6	No	Noted.
Are there any published or unpublished studies that we may have overlooked?	1	No	Noted.
	3	No	Noted.
	4	No	Noted.
	5	No	Noted.
	6	No	Noted.
Additional suggestions or comments can be provided below. If applicable, please indicate the page and line numbers from the draft report.	1	On pg. 11, the last sentence (lines 12-18) is very long and somewhat difficult to read. Consider rewording.	Thank you, this section has been revised for clarity.
		On pg. 11 (lines 36-41) as it reads currently, it is assuming that the intervention group received more frequent interactions. Unless this can be quantified that the intervention group did indeed receive more frequent care interactions compared to usual care, consider removing or restating, especially the last sentence of the paragraph.	Thank you, this section has been revised for clarity.
		On pg. 89 there are two typos. Line 33 "will" should be "with". Line 39 "is" should be inserted before "warranted".	Thank you, these errors have been corrected.
	3	This evidence based synthesis addresses medication adherence in adults with psychotic spectrum disorders, bipolar disorder, and PTSD. The questions are clinically important. The method for addressing the question is standard. It is unfortunate that the authors did all of this work, only to find that the literature is so poor that few conclusions can be drawn about interventions for these populations. Nonetheless, knowing that more well-designed and –conducted studies are needed is an important finding for researchers and policymakers. Several suggestions for improving the readability of this report are detailed by	Noted.

Question Text	Reviewer Number	Comment	Response
		section below.	
		Executive summary Study selection: • please address design of studies that were included. Consider using PICOTS terminology; interventions and comparators are not described but should be.	Thank you, this section has been revised.
		Results: • It is difficult to understand the take-home message from each comparison due to the lack of clarity of writing. Each section describes the evidence in a confident manner, which is later undermined by "but the strength of evidence is poor." It would be helpful to describe the strength of evidence first so that the reader can keep this in mind as reading the conclusions about the findings.	Thank you. Our summaries at the beginning of each section include a statement about the strength of evidence, and strength of evidence is detailed in subsequent tables (e.g., Table 14).
		Results: • Wording of "Of the 518 clinical trials identified…" it is unclear how these are different from the 152 identified. This reviewer assumes that the 518 were identified from clinicaltrials.gov but is unsure. Please specify the source of each.	Thank you, we have revised this sentence for clarity.
		Results: • Unclear is the use of "controls." Comparator might be a better term. There is heterogeneity in comparators, but the use of the word "controls" seems to imply that they are similar across studies.	Thank you. We have changed the term controls to comparators.
		Results: • Use of "Compliance Therapy" as a proper noun is confusing. Is this a standard behavioral approach? If so, what is it?	Thank you, we have revised this sentence for clarity.
		Results: • Unclear is the criterion for determining whether a study was considered significant. Is it effect size or type 2 error rate?	Thank you. Significance was determined according to the individual studies, and given the heterogeneity amongst studies and the qualitative nature of the review, we did not compute summary statistics. Tables in the main report (e.g., Table 4) provide data for clarity.
		Results: • Please do not use the phrase "trend" when something was nonsignificant. Many published studies are underpowered, so trend could be misleading.	Thank you. We have removed the term trend from the report text.
		Results: • System-level intervention definition is described as including e-monitoring, yet in the results, e-monitoring is listed under technology interventions. Here and in the larger report, the authors need to be clear by what e-health interventions are and whether they are patient or system-level. This reviewer tends to think of them as patient-level.	Thank you. We have revised this sentence for clarity.
		Results: • "Two RCTs examined e-monitoring…" Compared to what?	Thank you. E-monitoring was compared to a variety of comparators in both studies. We have added this language for clarity.
		Results: • Under technology interventions, the authors seem to be confusing	Thank you. We have revised this sentence for clarity.

Question Text	Reviewer Number	Comment	Response
		outcome with intervention "One study reported both a significant…"	
		Results: • P.7 section d: what was the finding related to the four studies?	Thank you. We have revised this section for clarity.
		Results: • P.8 section e: What is the effectiveness? It seems that an incremental cost effectiveness ratio is needed because the cost information alone is not helpful if comparing very different interventions.	Thank you, noted. As we conducted only a qualitative synthesis, we did not compute summary statistics not included in the original papers.
		• Table 1: system-level intervention: this needs to be defined, perhaps as a footnote. As mentioned earlier, it is unclear whether this includes e-monitoring, which is something that happens at the patient level.	Thank you. We have removed e-monitoring as an example of a system-level intervention.
		• Table 1: In this table, it would be helpful to have a column for comparator.	Thank you. Due to space considerations, we have added comparators to the findings column for clarity.
		• Table 1: SMS needs to be defined in the footnote.	Thank you, the definition for this abbreviation has been added.
		Discussion: • A more extensive discussion of the types of comparator groups and the impact on conclusions is needed.	Thank you. We have revised this section for clarity.
		Discussion: • Note that "medication" is often misspelled as "mediation" in this report.	Thank you, this has been corrected.
		Full report Introduction: • The series of paragraphs are not joined by transitions, so it reads as a series of paragraphs instead of a coherent introduction.	Thank you. We have added subheadings to address.
		Introduction: • There are so much data on adherence and factors associated with adherence that the authors do not build a strong case for the need for this review. If so much is already known, why is this review needed?	Thank you. This paragraph discusses the factors related to non-adherence, as well as what is known about adherence among people with psychotic spectrum disorders generally and in the VHA. The purpose of the review is to examine interventions potentially aimed at addressing these factors and increasing adherence.
		Study selection: • Which criteria are used to determine whether a self-report measure is "validated?" There is mixed opinion, for example, as to whether the Morisky measure meets criteria for validity and reliability, and this is true of other measures.	Thank you. We used Nguyen, La Caz, and Cotrell (2014) as a basis of self-report measure/validity. We have added this reference to Table 3.
		Study selection: • What is the difference between no treatment and usual care? Are these really different? This can be difficult to discern given that many authors do not define usual care. Usual care differs by site. Consider using the typology of control groups by Ken Freedland. http://www.ncbi.nlm.nih.gov/pubmed/21536837	Thank you. And thank you for providing the article. For populations such as these, usual care (most often including treatment such as psychotherapy, contact with a psychiatrist to adjust medications, etc.) often differs from no treatment. Tables in the full report provide a description of the comparator.
		Key Question 1: As in the executive summary, the meaning of "Adherence Therapy" and "Compliance Therapy" is not clear. Definitions are needed. Did	Thank you. This section has been revised for clarity.

Question Text	Reviewer Number	Comment	Response
		the studies using these types of interventions always come from the same groups of authors? If not, then did different research groups use the terms in the same way? It is important to recognize that what authors say they are measuring or doing is not always what they are actually doing. It is up to the systematic reviewer to make sense of it and then convey that to the audience.	
		Summary and discussion: As with the executive summary, there is tension between what the authors found and the risk of bias and strength of evidence. It is important to use precise wording to indicate why the evidence is poor or insufficient. It would be helpful to indicate primary reasons why, for example, the body of literature on (type of intervention in X population) is insufficient. Is it because the existing studies have high risk of bias, because there are too few studies, or other reasons?	Thank you. The reasons for strength of evidence ratings are outlined in the details sections associated with each type of intervention, and outlined in subsequent tables (e.g., Table 14).
		Limitations: The authors indicate that they used methodologically rigorous studies, but they included studies with high risk of bias, which seems to go against the statement that they only included rigorous studies. A more accurate statement would be that they included all studies (exclusion on the grounds of quality is an important limitation of some reviews) and then assessed risk of bias and used it to qualify their conclusions.	Thank you. We have revised this section for clarity.
		Discussion: The conclusions about the status of PTSD literature are confusing. On the one hand, the authors assert that there is limited evidence that adherence is poor in this population. That would seem to indicate that perhaps there is no need to evaluate interventions. But the authors go on to say that future research is needed to evaluate interventions in this population.	Thank you. We have revised this section for clarity.
		This reviewer is left thinking that the studies are so poor that we simply cannot draw any conclusions about any medication adherence intervention in any of these populations. Is that the take-home message the authors want to convey?	Thank you. Yes, given the limited number of studies examining specific types of interventions/intervention components, and that the strength of evidence for all but family and technology interventions (both low) was insufficient, our conclusion is that the current state of the literature precludes strong conclusions and recommendations other than related to the need for future research.
	4	Very thorough. Clear how articles were identified and selected. ROB ratings and how they are made are clear. Some suggestions for improvement:	Thank you, noted.
		Seems incomplete without a frank discussion of methodological issues including sample bias (most patients entering RTC's for adherence are more adherent than most patients);	Thank you. This section has been revised to include this discussion.
		Plasma levels are not appropriate for assessing degree of adherence (most patients take some medication which will show up);	Thank you, noted. We found that the few included studies assessing plasma levels differentiated adherence

Question Text	Reviewer Number	Comment	Response
			by the amount of medication found; for example, the levels of medication found in the blood compared to levels that would be expected in a fully adherent patient.
		Many studies do not use objective measures (pill counts, electronic monitors) and should likely be weighted differently from those using objective measures of adherence.	Thank you. These factors were taken into consideration, along with others, in rating the strength of evidence.
		While I understand investigating whether LAI improves adherence, the focus of LAI therapy is not really on improving adherence it is on identifying when non-adherence occurs. Moreover, more than even studies of other methodologies, studies of LAI have incredibly high levels of sample bias that set them up to fail.	Thank you. We have added a statement to the discussion regarding this point.
		It would have been good at the beginning to outline an example of a body of literature which indicates sufficient evidence. Citing AHRQ guidelines I don't think is enough for the reader, especially since everything came out Insufficient. What would a body of evidence need to do to be sufficient? Are two positive studies enough where one is at least low ROI and neither are high ROB? Are 3 positive studies needed with all low ROB? Is standard treatment an adequate control? Do studies need the same active comparator to provide solid evidence or can an intervention use different active comparators in different studies and be considered a replication of the main finding? It is not clear how the authors took the data and made this final determination.	Thank you. There are numerous variables associated with strength of evidence, and the process is too complicated to outline in the body of this report. In this review, many of the interventions were evaluated by only one study, or there were inconsistent findings. For transparency, we provide details related to our rating in the comments sections of our tables (e.g., Table 1).
	5	The report is well written and I believe it accurately reflects the literature on the key questions. The lack of literature limits interpretation which further limits reviewer comment.	Thank you, noted.
		Page 11, lines 38-41 and Page 88, lines 38-41: It may not be necessary to control for increased attention if is inherent from the intervention, i.e., cannot be separated.	Thank you, noted. We have revised this section slightly, and included this discussion to raise the possibility of a positive effect due to increased attention.
	6	I believe the review is comprehensive and well done.	Thank you, noted.
